I personally think it's unlikely that even if someone is trapped by the fancy-pants autotuner they bought, that they probably don't need an extra fifty feet of line to deal with it. In my experience even ten extra feet of line at 80M can noticeably change the matching taps I use on my tuner if you're working in the 1/4 WL 65 foot feedline range. Of course that extra ten feet might make their fancy pants autotuner crap out on 20M, etc. and I can see how someone might start feeling like the old lady that swallowed the fly. I would rewrite the song to "swallowed the autotuner".

My mistake, I apologize for misreading it. Yes, HP does reverse polarity, exactly as you say, when reflecting from the ground. Furthermore, the amplitude of the reflection is nearly the same as the incident wave (that is, the reflection coefficient is nearly -1), even when ground conductivity is relatively poor, especially at low angles. So the sum of the incident and reflected waves is near zero.

Unfortunately, the sum of a vertically polarized field and its reflection from finite conductivity ground is also nearly zero at low elevation angles, for different reasons. There is a component that propagates via surface wave, but it attenuates to essentially zero in a very short distance at VHF.

Ok all noted on the many ideas.

Here is one for you boffins:

After having a look at the circular turnstile type antenna with a groundplane ,I sent a request to the main manufactureers regarding using this in an inverted state for what I wanted to do on the repeater.Still yet to get a reply and after a few months I guess they are still thinking about it.

If they advertised it so great for horizontal to near vertical satellite work then the same principle should apply if inverted.

Style of eggbeater looking at .

Wow, you do not like autotuners, eh?

I use both regular and autotuners, and both work pretty well for me.

Neither wear pants, fancy or otherwise 8^)

1. How are you thinking of mounting it whilst upside down? Even if you were to use a dielectric swan neck of some kind, you'd still have the feed line passing through the volume into which the antenna is intentionally radiating, so the radiation pattern would be upset to some extent. Of course, if you were willing to modify the antenna you could probably pass a co-axial feed line through an axial tube - but if you were going to that much trouble you might as well build the thing yourself.

2. Their statement that: 'Each of the two loops forming the antenna has an impedance of 100 ohms, and when coupled in parallel, they offer an ideal 50 ohms impedance. We will use the properties of a quarter wavelength coax line to achieve a 90 degree phase difference between the two loops in order to obtain circular polarisation.' is a bit suspect. This would be true for a half wavelength of line, indeed that is the basis of a very common form of balun, but a quarter wavelength of transmission line will cause an impedance transformation. If they use 50 ohm cable then a quarter wavelength will transform 100 ohms down to 25 ohms, and when this is connected in parallel with another 100 ohms the result will be 20 ohms which is presented to the feed line. Not a particularly good match!

My suggestion is: if you intend to purchase, proceed with caution and keep asking the proprietor the questions you want answered.

The autotuners that the neighboring hams have do not have knobs. They just have a little button you push and then relays chatter and it either succeeded or failed. There's a little LED idiot light to tell you that it succeeded or failed.

I myself do not understand how a piece of radio equipment does not have knobs. Or how it has little blinky LED's but no meters.

My homebrew tuner has alligator tips for selecting the turns on the output link, as well as plug-in link-coupled coil sets for each band and of course knobs on the variable caps. IMHO if a tuner has plug in coil sets and alligator clips then you know you're cooking with gas. I was looking a a picture of a station in the 1972 ARRL handbook last night and realized that my tuner looks almost identical to the one in the picture (which itself was probably 20 years old in 1972).

OK - I've just noticed they specify RG62 for the quarter wavelength of line, and that has 93 ohms characteristic impedance. It would transmform 100 ohms down to 86.5 ohms which, in parallel with the other 100 ohms, would yield 46.4 ohms. Better.

Those are simple indeed. My autotuner has channel memories, an analog
meter and a cool little lcd meter that tells me how much inductance and
capacitance are inserted in the circuit. plus I can manually adjust
both. It's pretty cool in fact.

> I myself do not understand how a piece of radio equipment does not

I certainly don't have anything against old school radios and tuners.
Dunno if you have yours this way, but I would be inclined to mount that
alligator clipped tuner coil on a nicely finished wood base, and go
really old school pretty with it. Maybe make the coil supports out of
the same type wood turned to a dowel or maybe even polished glass or

plastic. If yer going old school, flaunt it!

Anyhow, it's all good, old or new. Gives me a lot more to mess with since I like both.

You probably need to answer the questions you were asked before anyone could advise on matching, like what's the length of the antenna?

Also, is this for pirate radio?

Chris

Hi:

A month or so ago I say a PBS piece on fractals. The piece claimed that the "technology" is used to make the antennas for cell phones.

Have any amateurs used "fractal technology" to form their antennas?

Also, I note that "they" market HDTV antennas that are about the size of a book. Do these things work? What's inside them?

Yours,

JLG

-sigh-

Any? Yes.
Many? No.

>Also, I note that "they" market HDTV antennas that are about the size of a
>book. Do these things work?

They work about as hard as Bernie Madoff worked.

The most enthusiastic fractal supporters here are those who never
built any, couldn't show you a design if they were forced to google
for one, and pound their breast about how modern inventors are reviled
in their own neighborhood. The most successful merchant who has dared
post here would sue you if you tried to make your own.

> What's inside them?

Wire (metal). Same as any antenna.

What makes you ask?

That might be true. There's certainly material on the www about research
into fractal antennas that can be Googled, such as
http://ceta.mit.edu/pierb/pierb14/07.09030802.pdf

> Have any amateurs used "fractal technology" to form their antennas?
>
> Also, I note that "they" market HDTV antennas that are about the size of a

As you may realise, terrestrial broadcasting provides a large margin for a
lot of households which makes it possible to receive good signals in some
areas using a dead sheep. Consequently indoor television antennas are sold
in a variety of styles and, at some locations, some of them work - even if
they have meagre electrical characteristics. Unfortunately, there is a
tendency for unqualified folklore to arise about antennas that appear to
work (in particular circumstances). The DVB-T system used in Europe is
particularly resistant to multipath distortion, which helps.

Some book-sized efforts contain a PCB bow tie in front of a plane reflector.
In others, the shapes of the elements are fiddled around with like
http://www.instructables.com/id/How_to_make_a_fractal_antenna_for_HDTV_DTV_plus_/

For 'educational purposes only', you could try these two programs. One
calculates the impedance at the feed-point of an inverted-L end-fed
antenna, and the other calculates the values of the L and C which you
need for an L-match tuner circuit.

endfeed.exe
l_tuner.exe (that's L-TUNER-EXE)

These - and many more wonderful programs - are available from this
website:

Wow. Been a while. Last time I saw or wrote anything here about fractals was over ten years ago, and someone in the group threatened to sue me/everyone who was not a supporter of the technology.

I do know that I have seen mention of this technology relative to hand held ATSC receivers for mobile video (cel phones, etc)

Yep. The advantages of fractal antennas are small size and wide
bandwidth. These are the prime requirements for cramming an antenna
inside a tiny cell phone. Making it work for 800/1900Mhz cellular,
2.4GHz Bluegoof and Wi-Fi, and possibly for TV, FM, WiMax, etc, is not
easy.

>Have any amateurs used "fractal technology" to form their antennas?

Not intentionally, although many antennas (and towers) somewhat
resemble a fractal, especially when they crash to the ground. Same
with some "low visual impact" cell towers. To the best of my
knowledge, hams are not cramming broadband radios into packages the
size of cell phones.

>Also, I note that "they" market HDTV antennas that are about the size of a
>book. Do these things work? What's inside them?

Sure. So do rabbit ears, clip leads, and coat hangers. If you're in
a strong signal area, almost anything will work, including a fractal
antenna. However, if you're in a weak signal area, or are plagued by
reflections, the more traditional designs are more useful.

(Disclaimer: I've never built a fractal antenna).

I recall a 10 meter fractal antenna. Strange looking thing. Disappeared some time ago from the web.

It's interesting that they call fractals "technology". Any of us could generate a usable fractal, and form some wire along that pattern, and make something. "Fractal" is no more technology than is "dipole".

There is a fellow who used to post here who has a company that makes such antennas. When I first came to this group, there was a war winding down. I never had any problems with the guy, but whoeeee the arguments were running hot.

But on the antennas themselves, they work, but they are not a substitute for a lot of other high performance antennas. All antennas are compromises, and Fractal ones are all about getting an antenna into a small space. The are mostly UHF also. That ten meter antenna was the exception, not the rule. HF? Imagine a 160 meter Fractal. No matter how it's done, it's still going to be big. If you have a small box running at UHF, you might think about putting a fractal (or it's cousin, a small random pattern antenna) in it. But if you want to run 80 meters in a small yard, there are better ways of doing it.

> Also, I note that "they" market HDTV antennas that are about the size of a
> book. Do these things work? What's inside them?

Define work. 8^) *Real* close to the stations? then probably. As for what's inside, if there was any design at all, probably a dipole cut for the approximate frequency. But that's a guess. IMO they are a wast of money.

Regarding the mounting , running the feeder out from a concrete microwave tower one can run the feeder from the top or bottom of the antenna.

It's not entirely a myth -- fractal antennas can be small and have wide bandwidth. But my dummy load is small and has wide bandwidth. What makes that an "advantage"?

You can take this to the bank: Small -- Broadband -- Efficient. Pick any two.

If the wavelength is 209.6 m then those dimensions sound like 0.21 and 0.1 of a wavelength so now I understand: the total length is 5/16 of a wavelength, not 51/16 as you wrote before.

Why don't you make use of the programs Ian Jackson offered, for educational purposes as he put it.

If this is pirate radio then you probably don't care about the audio quality, so there's no point in me banging on about keeping the Q of the system low.

Chris

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Oh, being in PA kinda limits my access. My Sons of Norway exposure was mostly because a relative was a member. I really liked those folks though. Garrison Keillor just about has them pegged - although the folks I was around liked to party a bit more.

My favorite story from those days is how when I first meet a Norwegian, they would tell you in a couple minutes if they like you or not. If they like you, they next thing they do is buy you a drink. I eventually told my father in law (the member) that we had to limit my meeting more people to the weekends, or no more than 2 an evening.

Hello,

It can or cannot. It depends on your required coverage area, soil characteristics and ground network. Assuming local coverage, it will definitely work less then a vertical quarter or half wave fed over a very good ground network.

When you have a relative bad ground circuit, you may only need a capacitor in series with the antenna wire to do the matching. When you have a good ground, you need an additional inductor.

When you provide some more info, you might get better feedback.

Best regards,

Wim

Only an idiot would do that. And a bigger idiot wouldn't
be aware of the free usenet servers. Esp. since there
was this big discussion about them on 0.Verizon when
the alt groups were pulled over one year ago.

Base is wood (polyurethaned pine) and coil supports are polycarbonate.

Polycarbonate is so way better than the polystyrene insulators I had
when I was a kid.

Yeah, pretty cool!

> Anyhow, it's all good, old or new. Gives me a lot more to mess with
> since I like both.

I am way overwhelmed with old radio stuff, would never have time to
play with the new stuff :-).

One of my neighbors (older than me but a far more recent ham than I
am) has a new LCD-screen radio and he gets all excited whenever he
finds some new software parameter he can access through twelve layers
of menu buttons on the front panel. I just kinda nod my head, I don't
want to dampen his enthusiasm, but I don't really know what he's
talking about :-).

Hi Jerry

Very good question ,and I do not have any information regarding their comparison.

On this tower due to the size and isolation I would have to split the feeder and have a minumum of two or more antennas around the tower . (Toer is 10m in diameter with steel reinforcing - high front to back isolation)

For this specific case , a Lindenbald would perhaps have too much horizontal space to mount a number of them around the tower.

Unless you are assuming that one uses one antenna split over the 4 , equally spaced around the tower.
Again this is a good question as under normal circumstances one does not have the high isolation between the elements .

I could use a 1:4 wilkoson and mount folded dipoles at skewed angles , so at any one time a distant station should see at least two of the 4 .

This is a lot to ponder about .

2521. Smith Chart program for Macs

Newsgroup: rec.radio.amateur.antenna

From: David Ryeburn <ryeburn@sfu.caz>
Message-ID: <ryeburn-D87D0A.15073301102009@morgoth.sfu.ca>
Source record: 12633

It's available, free, at
<http://www.microwavemac.com/Site/Smith_Chart.html>. I noticed that the
documentation file, in Rich Text Format with attachments, is about twice as
large as the program itself!

He also has a program for designing Butterworth or Chebyshev filters, at
<http://www.microwavemac.com/Site/Filter_Designer.html>.

Both programs require Mac OS 10.5 (Leopard) and presumably work under 10.6
(Snow Leopard) as well. I checked, and the Smith Chart program refuses to
run under Mac OS 10.4 (Tiger). I wouldn't be surprised if, with a little
fiddling, the programs couldn't be made to run under Linux.

This week end is going to be wet and cold, so I thought I would give
you a radiator to play with if you are willing to make something for
yourself.
Get yourself a piece of aluminum mesh used for window insect stopping
entering your house. Soak this piece of mesh in some watered down
muriatic acid (approx $5 a bottle at a hardware store This is to
remove the insulating coating so it becomes conductive. Now this mesh
is woven so it helps to compress the strands together by tapping with
a hammer. Connect a MFJ259B to the base corners and scan to see where
the resonant frequency is.
I used a 8" x5" piece of mesh and it was resonant from about 110 to
140
MHZ so it is quite broad banded and easy to find the resonance The
vertical strands carry the applied current and the capacitance square
holes in between is a electrostatic field around which the
displacement current flows. What you have, basically, is a full wave
dipole folded very closely upon itself to form a closed circuit with a
low impedance. This is basically a transmission line if the ends are
open. The cross jumpers take the place of dielectric spacers that are
present on a open transmission line so that they may enclose an
electrostatic field created by the displacement current. The vertical
strands are really in series ,so you have effectively placed a long
length of wire into a small volume which you may shape into any form.
To play with this further, place it above a conductive sheet and note
the changes. Then try pinning it together into a cylinder and note the
changes.
Have fun playing with it.
Looking at the physics side of things. When a particle is generated by
the Sun it goes to the border and even tho it is extremely small it
breaks the border by applying a straight force vector together with a
circular vector. This same combination repeats itself when current is
applied to a radiator which also produces a circular current. These
same vectors are later repeated with gravity in combination with
rotation all of which are per laws of Newton. The particles that
escape from the sun sheath conductive materials on Earth. This is
explained by making the Gaussian field for statics a dynamic one so
that it becomes the same as Maxwells laws. The combination of fields
from the applied current when intersecting the electrostatic field
dislodges particles by elevation with spin while accellerating to the
maximum speed which is that of light so the particle can take on a
straight line trajectory with spin where the Gravity vector is
cancelled.
Elermentry explanation of the weak force in the Standard model

What I'd like to know is how the vertical and horizontal strands know which role they are supposed to play? And if I rotate the mesh by 90 degrees but still keep the feed the same, why don't those roles change?

What if the whole thing is parallel to the ground? It should stop working completely. Hell, it could even explode for all we know. The poor strands wouldn't know what to do and the energy would build up until there was too much and - BOOOOOM!!!

And what happens if this antenna is in space? Does it stop working? Do the bits remember what orientation they used to be in when they were on earth?

Or is this all just some fantasy dreamed up by someone who needs serious medication?

Most likely the latter.

Why? Hams will deny it without trying. Physics! all will deny it as it comes from an engineer.
Somewhere in between some one will try it. Then curiousity will take over and the question will be asked " Why is this" And then the naysayers will answer" you didn't measure it correctly or the MFJ 259B was not intended for that" Then a person with a small garden will get a bigger piece to try it out on Top Band. "You have to prove it" say the naysayers
together with " you are an engineer so you can know nothing of physics" "Well I just followed Einstein" I said " He was convinced that the secret of the weak force lies with radiation" So you are comparing yourself with Einstein?" said the naysayers. So I said that "Gauss showed the way with the static field to which I made dynamic and added radiators
so that it became the same as Maxwells law since I maintained equilibrium!"
":You can't do that" said the naysayers " that is not in any of the physics books" ":I know "
I said " be patient ": What you seek you will find" . Now who is the next person to argue with Einstein and his prediction? Newton stated that every action has an equal and opposite reaction. The big bang started from inside a arbitrary boundary. Equilibrium was broken when the smallest of particles from the Sun ventured towards the boundary. When this happened that little of little particle became an opposing force which was off centre from the opposite force such that it also applied a torque vector (spin). That chain of force vectors end with the combination of gravity with the rotation vector of Earth, where the chain of events passed along the phenomina of radiation as predicted by Einstein. No. I am certainly not going to argue with Einstein. PS try it for yourself with the many computer programs so you can argue that the programs are wrong where only the vendor is left to argue against. Now you have a bigger question, How does a particle propagate while neutralizing gravity?. Ponder on that for a while. Now for the biggy Will Cern change there minds when they read this? No we are going to find the Higgs field that nobody has found even if we have to blow up the tunnel. We want five forces to make up

the Standard Model so we can go down in history!

I saw on in a Big Box store (Target or Wally World). It said "Patented
Technology."

I was thinking of something for use in a high rise condo now vacent. When
I lived there years ago it was possible to get about 10 or so TV stations
with whatever rabbit ears that came with the TV.
>

I have been around for awhile. I rememble a "miracle" TV antenna that was
just a weight covered with plastic, for example. So I am wondering
whether there is something that works like a "miracle" or are rabbit ears
the state of the art for a antenna. Trouble is that with flat screen TVs,
there isn't any place to put rabbit ears!

What a nonsense.

Everything resonates somewhere,
just give it n * lamda/4 dimensions.

A piece of wood would do it, when it rains.

Yup. I know the feeling. Poulsbo had more characters per square inch
than any other place I've been. I had the retired marine sargent who was
afraid of ghosts - but nothing else, the most people loving person I'd
ever seen, "Shitbird", the mumbling old gent who wasn't happy unless he
had you rolling on the floor laughing, and a host of others. They were
all much older than me at the time so they're probably all gone now.

If you're close, try the rabbit ears. If not, try a small yagi. Fractal antennas are probably not the solution for you. One might work, but high performance is not what they are about. They are about large bandwidth in a small space. But it's the definition of small space that is the issue.

Hardly a recommendation when the technology is a corriolis force
applied left hand threaded (gaussian) screw holding the maker's plaque
to the merchandise.

Calling it fractal won't add a horizontal surface to a flat screen to
sit the antenna on; and it won't remove the necessity of turning the
antenna 90 degrees to catch the signal and poking you in the eye with
"patented technology."

Take a conventional rabbit ears antenna, lay it in the driveway, drive
over it for the next of the week; and DON'T report here how well your
fractal works when you put it up or you might get a cease-and-desist
notice from a lawyer representing a recent Nova whore.

Hi

An OM is telling me that there was in the past a version of the
MFJ-949E who had a variable coil using a cursor instead of a switch to
tap the coil as now.

Any comment on that?

Thanks de Pierre ve2pid@videotron.ca

I consider any balanced symmetrical antenna a fractal.
Even a dipole.
What many consider as a fractal antenna, I consider a linear
loaded antenna using "creative" linear loading.
Is creative linear loading superior to the usual linear loading
one might encounter? No one has ever proven this to be the
case.

They even held contests on this group to see who could
build the best "fractal" antenna. It was shown that even
random designs performed just as well or better than
the designs offered by the local fractal guru at that time.

Fractal antennas are a viable antenna to use in tight
spaces, but no one has ever proven that a fractal design
is any better than a random linear loading design.
Not even once that I can think of.

I could cover my eyeballs, and scribble out a symmetrical
design on a piece of paper, and most likely it would
perform just as well as a "guru" offered fractal design.
A few here have proven this to be the case.
What fractal antennas are really good for is when you
have DOD and government contracts that require very
small antennas, and need something which seems
"special" in order to win these contracts.
It doesn't really matter if the antennas are superior to
random design linear loading. All that matters is that
the ones that sign checks believe it to be the case.
Kind of like the government spending $342.95 for a

hammer. It doesn't matter that the expensive hammer
is no better than one you can buy at Home Depot for
a fraction of that price. The hype overrules the reality,
and clouds the minds of those that sign checks.
Needless to say, the ones that sign checks don't have
a clue whether fractal antennas are worth the money or
not. They could care less. They see it as redistributing
wealth. :/
To me it matters not. I use manly full sized antennas,
and I'll leave the little fractals to ones that want inferior
performance.
Heck, if I could sell boatloads of inferior antennas for
boatloads of money, I could probably live with inferior
antennas too. :/
I'd be laughing too hard on my way to the bank to
worry about having a decent antenna for my radios.
Or HDTV.. Another groaner for me. HDTV antennas..
What in the wide wide world of sports is an HDTV
antenna? Do digital signals follow different rules than
analog signals? Groan... Just another example of
getting people to write checks for something someone
claims as "special" when it's not. :(

I remember when color TV was the rage and color was added to the name
on all the TV antennas. Sometimes there was actually a stick on
"color" label on the box.

One thing that has not been mentioned is most of the small HDTV
antennas (at least the ones I have seen) include an RF amplifier. W/o
the amplifier these antennas' performance is abysmal.

Is the model description you give correct, or have you combined two models, the MFJ949E and the (Deluxe) Versatuner II (MFJ969 IIRC)?

The '949E uses a switched coil, and the '969 uses a roller inductor, IMHO a pretty poor roller inductor that uses insulating material that softens when it is hot and makes the tuner prone to serious damage under some poor operating conditions.

2541. EZNEC Ver3 Automatic Save

Newsgroup: rec.radio.amateur.antenna
Date: 2009-10-02 22:35:22 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <ha5v7opuf1@news.eternal-september.org>
Source record: 12503

I have found that there is no such thing as "automatic save" unless you are in LAST.EZ. If you want to take an existing named file and improve it - - okay click on the file and work on the wires, transmission lines and source tabulations, but be sure to SAVE AS and choose the same filename and just replace it. If you don't, the file won't get updated. I learned this after assuming opening a filename meant anything I would do would be placed under that filename - - like it would if you were in WORD, but no, it's not saved, and if you open another filename, the work you did will be lost - - in my case, all 32 wires, 21 transmission lines and 2 sources to enter data for 2 designs - - and you'll have to do all of it over again. I even printed out the description of the file - - it was all there - - but the next time I went to look at it, it was back to the previous file that the new design had been started with - - no update!

Roy, you may or you may not fix this - - I guess it's been this way for a long time - - so you probably have your reasons. It's just that it's not like WORD, and I feel WORD is a preferable model. Of course once you know about the problem, I guess it's not a problem - - until you forget and lose your work - - so I'm lighting the candle. I have never lost an update to a WORD document. (You are prompted to save it, if any change has taken place).

That would seem to be the intent of the acid bath and hammering, but who knows, maybe it was a diamagnetic hammer (not Maxwell's silver hammer certainly) pounding in the particles that would someday under equilibrium fly off like Tinkerbell's fairy dust.

>Snake oil spin.

A new corriolis effect?

Perhaps Obama can slip over to Stockholm and get Art a seat at the next Nobel awards. Something tells me that the Sewer rats of Rio (a nod to Reggie) will snag the prize from under his nose.

Never mind.! You don't own a MFJ but you anticipated the answer anyway
when applying a DC current. Excellent, you are a antenna guru.

Beginning with version 4.0, introduced more than 5 years ago, EZNEC prompts you when you end the program or open a new file, asking whether you want to save the current one, if the description has changed since opening the file.

I won't be making any more changes to v. 3.0.

What did the instrument say exactly? Or is that covered by your patent?

What leads you to believe that it indicated rezonunz?

And if it did, why would you think that helps confirm your nonsensical
view of the world?

Just made another similar size sample made of brass with a diamond
perforation and I got it down to 45 mhz where reactance was zero and
the resistance was 20 plus. I suppose I could get it to go below 45
Mhz with more manipulation but it is getting late. Seems like only a
few own a MFJ 259B which makes for silly questions and comments. Oh
well.

And what were you driving it against?

Was it connected to just the center pin on the PL259?

If so, what was connected to the ground side of the instrument?

You really make yourself look so stupid with questions like that. Or
maybe I should say "so dumb?" You "may" have made it out of high
school "may", but for evidence of higher education you could get a
diploma from a Honduras University for just pennies. Probably sent off
a postcard for one with a Honduras postage stamp on it just to impress
them.

Just twigged on the key phrase "I got it down".

What is that supposed to mean? "I bent it?" or "I moved it next to this nice old cast iron radiator"? What?

So he adjusted it in an undefined manner.

And what size "diamond perforation"? What angle? What percentage perforation? What thickness is this sheet? (Almost a bad pun)

You may have bought one but you have never used it as shown by your
silly questions.
You have lied so much in the past.
I presume you live alone or maybe you are homelessso cut a square from
the mesh on your window and introduce it to what ever you bought with
a piece of coax with a connector at one end and the shielding and
center wire separated at the other end. Yes, just for fun connect only
to the centre pin and stand back as it surely would explode. My
version of the MFJ doesn't say anything so I have to read the meter.
Since your one "says" it all ask what it is measuring! Do you think
you can do that for yourself? I imagine many hams have already tried
it and are laughing their heads off over you and your questions.

When I've made claims, I've generally associated numbers with them. If someone should challenge me on one, I would respond to them with where the number came from. We could then have a discussion about it, and if it ended up on this group, others would get to make cogent and lively comments.

And hopefully some would learn from some who knew. And those who presented verifiable evidence would be acknowledged by those that didn't have it. And some would disagree on nothing but fact, and some would disagree just for the hell of it. And so on.

But there is a consensus on what works and why. The disagreements are pretty much on just the fine points and about 80% because the OFs in question like to do it and have the time. At least it appears that way. I'm not bothered by it, and I think most of the regulars aren't either. And some of it is quite amusing. The next button isn't hard to click.

Which leads to me saying, Art, ssppppsssspppppspsspspspspsp!

Thanks. That's the best description I've ever heard from you. Now the coax type, and how long. and it's orientation and distance from the ground or large metallic things, and your position and weight and height and other things like that in the local environment and then we might _begin_ to be able to duplicate your place of testing.

i have an inverted L antenna for medium waves. i would like to ground
the static high voltages. the antenna has static high voltages when the
weather is not good.
i am looking for a easy system to ground this voltages and to protect
my transmitter and the tuning circuit.
i had seen a schematic with carbon resistance about 10kohm which is
connected between the antenna and ground. this solution is ok? do you
have to propose any idea?

Yes, fine as long as you don't connect it somewhere where the system
impedance is high (like the end of the radiator!). Surprising you should
ask something so basic when you claim to run an engineering 'corporation'
http://www.tzitzikas.webs.com/

Doing so would act as a static drain, but may not be effective at
preventing damage to whatever your antenna is connected to if there
should be a nearby lightning strike.

A better approach for that might be to disconnect the antenna from
your equipment during lightning conditions, and connect it a good, low-
Z, earth ground.

I prefer EZNEC the way it is to an Automatic Save
to the original filename since that would wipe out
the pristine file one started with.

An improvement might be to ask the operator, upon
exit, if he/she wants to save the present file.

May well be, but it isn't in Europe. Are all gmail users in the USA then?

Then you should be able to duplicate Art's results without knowing the
parameters of Art's test. Sez who? Well Art of course! HI

I own a MFJ-259B and find it to be an useful tool. The device's OOB
accuracy was found to be lacking but after re-calibration all was FB.
Perhaps instrumentation errors are helping to 'confirm' Art's
contradictory theories and hazy explanations.

That's the one that often bites me. Make some changes to a model, and on exit you don't get prompted to save it. Next time you run EZ it's there as LAST.EZ, but if you now open a new file you don't get prompted to save LAST.EZ, so all gets lost. A prompt to save on exit would be nice.

2570. Fishrod anìtennas - transformer and twin-lead

Newsgroup: rec.radio.amateur.antenna
Date: 2009-10-03 19:08:57 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4ac7a166$0$1103$4fafbaef@reader3.news.tin.it>
Source record: 12532

Use of fishrod antennas is getting more and more common to cover all bands 7 ... 28 MHz, including WARC. The typical length of the radiating wire is about 25 feet, that is about one quarter wavelength at 10 MHz.

On lower frequencies (e.g. 7 MHz) that antenna shows a low radiation resistance and a strong capacitive reactance. On higher frequencies resistance goes up and down with frequency, showing very high peaks, and reactance does the same, though obviously with a different pattern.

Typical configuration used is:
- 1:4 transformer (balun or unun) at the antenna
- 300-ohm or 450-ohm flat twin-lead
- tuner at the transmitter

SWR is generally high, except on certain specific frequencies (which may not fall in the amateur bands).

I would like to hear some opinions on the usefulness of using the transformer and the twin-lead. My arguments are:

- above 10 MHz, where impedance is generally fairly high, the transformer could (??) be helpful to reduce SWR, but below 10 MHz it should be harmful, as its transformation goes on the wrong side.

- use of the twin-lead is usually justified by its low attenuation, that limits the extra attenuation caused by the high SWR existing on the line. In my opinion the 300-ohm twin-lead attenuation is reported to be low mainly because it is measured in presence of a 300-ohm load, that draws low RF current. But in the subject application, where the antenna impedance is uncontrolled, what should count is the ohmic resistance of the twin-lead conductors which is not particularly low due to their fairly small diameter. Wouldn't an RG-213 do better than the twin-lead?

Thanks for your comments & 73

Hi

I am looking for a Cushcraft 5 element A50-5S six meter beam to cannibalize and repair my A50-5S.

I am out of work for medical issues so funds are tight right now I hope I can find something and do a repair cheap as possible.

The boom is in 3 sections, I am missing one end. Aluminum Tube 1-1/4 X 50"

I am missing the entire REDDI (GAMMA) MATCH Assembly, on page 5 of my original instructions.

2 end caps (plastic) go on each end of the boom.

My son Darien - KDBKMF just got his call and wants to talk on 6 meters On both Voice and CW . We just cant afford to buy a new antenna.

I am cuting a wire to a inverted "V" today. He really wants a yagi. I dont blame him at all.

We live in Toledo Ohio it would be nice to find parts.
thank you
Rich NF8V Toledo Ohio

Did you know that from prior communication with the OP or is there some data in his posting that gives a clue to that fact?

For the countries in ITU Region 2, the Americas, there will be FCC and other documentation some of which may be available, and some of which may be available free of charge; there is also some amount of comment about polarisations like http://www.televisionbroadcast.com/article/67946.

For many of the countries covered by the Geneva 07 ITU-R agreement, the 'frequency allocation tables' include polarisation details and can be accessed from the national administrations via the ERO web site http://www.ero.dk/6EB60FD0-D703-42F6-97C1-41FD3713F2B0.W5Doc?frames=no&; they can generally be downloaded free of charge.

Hi Tony,

Good of you to notice that the 1:4 can also be viewed as 4:1 (or did
you notice?) with it reversed. This is not strictly so, as the
classic BalUn consists of wound transmission lines with characteristic
Z at the geometric mean of the load and source Z. However, lacking
this doesn't always stop the experimenter.

If your BalUn has already done the bigger job of turning a High Z to a
modest one, the common logic for the need for twin line has also been
diminished.

Working with, designing, and building BalUn applications demands a
good tool for validation. Do you have something that will measure Z
with accuracy?

That is obvious, but in common designs there is no provision (e.g. a relay) for reversing the transformer when operating on frequencies where the antenna resistance is lower. So the transformer remains there as it is, doing the opposite job of what it should do.

> Working with, designing, and building BalUn applications demands a

No, I am not building that antenna or doing any experiment. I am only trying to understand the rationale behind what people proposes and I am seeking advice from people having specific experience on the issue.

By fishrod antenna, I assume that you mean a telescopic fibreglass pole of about 10m height, used to support a straight or approximately straight (including a very coarse pitch helical) vertical wire of the same length.

This has a lot in common with the popular 43' vertical, just the lengths are different, and the frequency coverage will be different.

The use of a 4:1 balun on all of these things seems inspired by one antenna manufacturer's recommendation and supply of 4:1 voltage baluns for the application. Their site shows testimonials, and claims thousands sold. Eham reviews abound with glowing testimonials.

However... the application of a 4:1 voltage balun seems to me not only to lack design rationale, but to be quite undesirable in driving common mode current on the coax feedline, and potentially very lossy in configurations where the feedline is buried.

I discuss the use of an untuned vertical as a multiband antenna, and raise the insanity of the voltage balun application at http://www.vk1od.net/antenna/multibandunloadedvertical/index.htm .

Well, not intentionally I'm sure. As I've already stated in another thread
in this NG, for what it matters, I'm located near to London - actually a
stone's throw away from Epsom racecourse.

Have you come across anything useful published by the FCC about
polarisations used for digital terrestrial television.

Chris
I took your advice and sent an E mail to sci.physics research
explaining what I have found
and asking for comment. I am not a member of that group so it may well
not be picked up.
Tomorrow I will add to my home page.... Unwin Antennas..... copies of
both patent requests where the last one contains graphs of results of
mesh style radiators with other things. As time passes I will add my
other antenna patent requests from the past just for the hell of it.
Initial patent request costs were $515 each which is a lot less than
the UK and I believe it is about $200 for maintenance fees on each of
them due in about two years from now. I recommend that those with
EZNEC model the helical antenna shown as I am sure they will find it
of interest.
Regards
Art

Yes. http://www.fcc.gov/mb/video/tvq.html is the start page for most television queries for US, Canadian and Mexican TV stations. Type something relevant in the Call Sign block and press <Enter>. On the next page, click any of the station's lines and you will next be taken to a detail page (my term) with many specifics for the station, commonly including antenna polarization. (You may omit the callsign and instead enter a city, further downpage. Then, all that city's licensed stations will be listed and you can bring up detail pages one at a time.)

Just now, I determined that KTVU is Horizontal and KABC is Circular (H=V).

Please note that the detail page lists data for every major paper on file with the FCC (or neighbor government). That is, you find separate clusters of data for the station as licensed, plus any construction permits, applications, modifications, etc. Be sure of what you're seeing, as some of it represents planning that might never be approved or funded.

Some data will open in a new window; the coverage maps are that way.

Happy hunting,
Sal

re Weak force
Yes, it goes directly to the moderator so I imagine that it will take time. The question being that 2 vectors can be traced from the big bang to the boundary of earth. If it is not the weak force then where does it fit in with GUT? This also was predicted by Einstein with respect to radiation so if this is not it we have more searching to do. We will have to wait and see what the technical level is and it may well be as low as this group! Time will tell.

It's interesting to model this sort of arrangement, note the wide range of feedpoint impedances that will be seen on the different bands, and observe the feedline losses that might be incurred when it is directly fed with 50 ohm coax. If you then introduce an ideal transformer at the feedpoint and repeat the exercise you will generally find that feedline losses increase on some bands and decrease on others.

With the vertical length I tried, the effect of a 1:9 transformer was to limit the more extreme losses at the cost of making some very low losses higher. I guess over the several bands I tried you could say there was a net improvement with the transformer.

But one question would be how to build this ideal 1:9 transformer which maintains its transformation ratio and exhibits zero loss across the wide range of impedances and frequencies involved.

It is a question of interpretation. There are many computer programs that are used by hams
and they do quite well. But they generally are used for planar forms and not what Maxwell
proposed in his formulae, where accountability of all forces involved is a must.
So when these programs show that a radiator is tipped against the ground to arrive at "100% efficiency" then it becomes worthy of hams to review why this is the case. Actually it shows two vectors at work outside the earths boundary where hams have only taken into consideration of one, and that is gravity. So hams are now presented with an opportunity to re asses their position on antennas such that maybe returning to full compliance to Maxwells formula will provide a path of improvement with respect to radiation, where one can look at point radiation as the path towards smaller radiators. I have shown that reviewing radiation in the light of Maxwells equations, when compared to those of an extended Gaussian law as being equal, states that " A conductive radiator can be of any shape, size or elevation as long as it is in equilibrium" This obviously presents opportunities for hams to approach with advantage antennas over and above those used today. The sad thing is that the hobby has changed so much that the theme is not to explore but to deny change, because we have lost the base of curiousity and experimentation to the use of radio as a means of talking behind the shade of anonimity
where one can assume a station in life that they really have not earned.

Your conclusion is faulty. See
http://groups.google.com/group/rec.radio.amateur.antenna/browse_thread/thread/d419e5b91e29e0be

and...

> A conductive radiator can be of any shape, size or elevation as
> long as it is in equilibrium

Any conductor exposed to space will produce far-field EM radiation
from nearly 100% of the r-f current that can be made to flow along it,
in directions where fields from various parts of the conductor do not
cancel each other.

Those that will radiate most of the rated power of a transmitter will
have a high radiation resistance compared to the sum of the other
ohmic losses in the antenna system, whatever matching network is
required at the feedpoint to match the feedpoint Z to the transmission
line connected there, and a transmitter designed to supply its rated
power into that net load impedance.

Wire conductors and configurations that are small in terms of
wavelength necessarily have low radiation resistance. So systems
using them do not radiate a very high percentage of the available
power of the transmitter.

Some time ago I made a series of careful measurements of a transformer which was at the feedpoint of a multiple band antenna. At frequencies where the feedpoint impedance was very much different from the (purely resistive) design impedance, the transformation wasn't equal to the design transformation, and the transformer introduced both series and shunt impedance. At some frequencies, these effects were extreme, and the transformer acted nothing at all like an ideal transformer.

Modeling a system like this with an ideal transformer might be an interesting intellectual exercise. But that's all it is -- the real system won't behave anything like the model. You can extend a transformer's range of impedances and frequencies by using great care in the initial design and construction, then adding compensating circuitry. The job gets more difficult as the transformation ratio increases. I seriously doubt you'll ever come close to making a transformer anything like the one described in the last paragraph.

The amateur way is to build a system with a transformer, then figure out how to live with whatever you get. An engineering approach usually involves designing a system with predictable and repeatable performance, and that precludes depending on a transformer over a wide impedance range.

There's an interesting twist. We're finding that these amplified gizmo's
are creating problems. Too much signal for the amplifier, actually
degrading performance. And they amplify the local noise, which is much of
the real issue, Taiwan wall-wart supplies, etc...

And they amplify FM. Combine the right two FM's and you can wipe out
reception to a VHF high band TV.

It is amazing how mis informed so many people are.

Yeah, just ask the guy at Radio Shack. 50 years too late for that one to
have a chance.

Steve,

My article on the unloaded vertical includes a discussion of the unun / balun thing. I did run models incorporating an ideal 4:1 current balun, and found that coax loss is better on some frequencies and poorer on others.

The model is not directly applicable to a generic end user installation because the coax loss depends on line type, length etc, and the ideal balun assumption is not a good estimator for practical baluns with extreme loads.

I haven't published an article on the unun model, I should one day perhaps.

Practical baluns are likely to have higher losses under extreme operating conditions, and that will result in lower VSWR than otherwise, so the added complexity of a real world balun is that at those extremes, it will tend to be lossier, its transformation departs from ideal, and line losses will tend to be lower.

I have created a model of a practical ferrite cored 4:1 unun, and explore it with different core materials, dimensions, and windings. The models reconcile well with G8JNJ's experimental ununs and my own prototypes... but reconciliation on extreme loads taxes both Martin's and my own measurement capabilities.

I cannot guess what inspired the application of 4:1 voltage baluns to these antennas, much less why a reputable manufacturer would recommend the configuration which to my mind defies sound principles. Nevertheless, it does appear that thousands are successfully in use, and many hams have the QSLs to prove that an antenna that lacks sound explanation "works real good" anyway.

I do think there is good reason to apply a common mode current choke to such antennas, not to recommend them as a matter of routine (though they won't hurt much), but in some implementations one could expect a significant common mode current problem, and a commom mode current choke may be part of an effective mitigation.

As to whether a 4:1 transformation is universally better than 1:1, ideal or otherwise, I doubt it. If the coax loss is a problem, and it will be for all but lowest loss configurations), an ATU at the feedpoint seems the better solution.

In making the observation that loss helps to reduce line VSWR, which in turn reduces line VSWR, perhaps the only sensible design rationale behing the 4:1 voltage balun applied on the subject antenna is that it drives common mode current on the feedline, and in the case of a buried feedline (as they often are), the power lost in heating the soil tames the feedpoint impedance, reducing line loss. But, does that maximise system efficiency? (Though it may work in that way, I doubt the 'designers' had that in mind.)

Owen

Owen,

If I've managed to read my lab notes correctly, these were the differences in loss (ground+feedline+tuner) - with and without an ideal 9:1 transformer at the feedpoint - for a 33ft vertical over average ground fed with 50ft of RG213. I assumed ground losses of 20 ohms. Positive figures indicate that the losses were lower with the transformer:

160m -1.6dB
80m +6.02dB
40m -2.3dB
30m +2.1dB
20m +4.4dB
17m +3.86dB
15m -0.55dB
12m +1.6dB
10m +2.9dB

Of course this data was for one specific scenario, but I guess you'd look at it and say that for this case, on balance, the inclusion of the transformer was of benefit. But now factor in some realistic transformer losses and it might not look so clear cut.

73,
Steve G3TXQ

Steve,

Here are the input impedance and VSWR(50),Loss graphs for my model of a FT240 #61 with 12 bifilar turns with a 1000+j0 load.

http://www.vk1od.net/lost/Clip045.png

http://www.vk1od.net/lost/Clip046.png

Non-ideal transformation ratio is not a big issue for an unun used with an ATU, voltage withstand and loss are higher priority.

The balun loss data in the article at http://vk1od.net/blog/?p=568 was obtained by measuring the balun using a VNA, and creating a spreadsheet that solved the balun + load network for an arbitrary load impedance. The spreadsheet is revealing, as one can immediately see the broadband peformance of the balun with extreme loads, R and X in arbitrary combination.

What I do know is that it is superficial to describe a balun (or unun) with just two metrics such as 5kW, VSWR<1.5... but have a look at commercial baluns, that is how they are often (mostly) sold. There is the odd manufacturer that gives a loss and VSWR curve on a nominal load FWIW, but I have not yet seen any manufacturer publish a set of S parameters covering the operating range.

I am not naive about magnetics, they are challenging devices, but at least in the ham radio market, it is more black magic than good sense.

BTW, if you look at the loss graph for this device with a 1000+j0 load, and assume that it can safely dissipate perhaps 20W continuous, it is capable of less than 1kW continuous at 30MHz, but some manufacturers build such a transformer and rate them at 5kW or more. With a load impedance of 4k+j0 (eg a full wave dipole), the loss is even worse, and the continous power rating even lower.

Owen

Owen,

Agreed. But the "non-ideal transformation" will result in changed
feedline losses and tuner losses. May be better, may be worse :)

I enjoyed reading your balun loss article. "66% of the transmitter
power converted to heat inside the ATU" will be a surprise to many
folk. I can replicate almost the exact set-up you describe: G5RV >>
half-wave of ladderline>>4:1 voltage balun>>tuner; so If I can find
the time I'll try to measure the rate of temperature rise inside the
tuner case when it's handling 100W CW, and then stick a 60W light bulb
in the case and measure the rate of temperature rise again.

For the US, the FCC database tells the polarization (elliptical is
pretty common.. mostly horizontal, with some vertical component)

For instance, here's the stuff for KCBS-TV in the Los Angeles area:
http://fjallfoss.fcc.gov/cgi-bin/ws.exe/prod/cdbs/pubacc/prod/eng_tv.pl?Facility_id=9628

Horizontal pol

But channel 11, KTTV
http://fjallfoss.fcc.gov/cgi-bin/ws.exe/prod/cdbs/pubacc/prod/eng_tv.pl?Facility_id=22208
has Elliptical..

The search page is here:
http://fjallfoss.fcc.gov/prod/cdbs/pubacc/prod/sta_sear.htm

Yes but my question regarded the advantage of twin-lead vs. coaxial in that particular application where impedance is uncontrolled.

Almost always, but probably more often for the better.

BTW, I gave a brief description of the FT240 #61 12t unun, but didn't mention the winding details, they are 0.8mm wire spaced (centre to centre) 3.2mm and permittivity 1.2 which describes a winding with 0.8mm PTFE insulation for high voltage withstand, an 'ATU unun' in commercial talk.

Keep in mind that ferrite cores heat (and cool) very slowly. One could easily be fooled into thinking that there isn't much heat dissipated in a short test, but after an hour of operation, the core is still heating at a substantial rate. This is one of the things that saves the bacon of manufacturers of 5kW and 10kW continuous rated baluns, they are not usually called upon to operate at high duty cycle for long enough to reach the Curie point.

Calorimetric measurments are problematic, they sound simple enough, but latency my mean it takes hours to reach close to maximum operating temperature.

The greater worry is that this manufacturer, and probably some others, use thermoplastic insulation to support the coil, which could result in damage if you operate the ATU long enough to reach operating

temperature. Do so entirely at your own risk.

At one time, I had two identical ATUs, and I attached one with a 600+j0 load to the tx on 1.8Mhz and adjusted for VSWR=1 on the input. I replaced the load with another ATU backwards and with a 50+j0 load and adjusted the second ATU for VSWR=1 on the input to the first ATU. I then read the power into the 50 ohms load and out of the tx using a Bird 43 and calculated the loss. The loss in the first ATU under those conditions can be approximated by allocating half the total loss. This test indicated quite high loss, and the case was quite warm near the balun after just minutes of testing. BTW, this was the same type of ATU as in the article you mentioned earlier.

In the example article, about 26% of the tx power is radiated on 80m. That sounds pretty awful, but it should be seen relative to say 80% as a reasonable system efficiency for a multiband antenna.

Concerning a TV station using elliptical polarization is there a
purposeful phase difference between the horizontal and vertical fields
or is it simply just dividing power between horizontal and verical
radiators with no concern as to phase relationship

Tony, it depends on the details of your scenario, and may be different at
different frequencies.

Unless you believe in the myth that ladder line is *so* low in loss that
you *never* need to consider it, you need to calculate it out to really
know... it is not a no-brainer as we say, in fact it is a quite complex
problem to solve (mainly quantifying the loss and transformation in
transformers which both Roy and I have mentioned in this thread).

BTW, from time to time I see articles that recommend twin line for direct
feeding a ground mounted vertical (ie without using a balun at the feed
point). It is as insane as using a 4:1 voltage balun with coax at the
base of such a vertical, because both types of feed drive substantial
common mode current on the feed line. A review of such an article is at
http://vk1od.net/antenna/multibandunloadedvertical/BSUM.htm , this one
using a magic ingredient, Belden 8222 twin feedline which Belden ceased
manufacturing. But... I am sure some hams have got the QSLs to prove that
it "works real good".

A friend of mine cited a claim in a brand new book, "The Lost Symbol" by Dan Brown. So said, in it is a claim of a new weapon of choice that is installed in some USA military helicopters which is cable of aiming an actual EMP pulse at a target below that destroys computer and electronic equipment of focus to the pulse! Same as a 'normal' 30Megavolt/Meter EMP pulse from a nuclear device, or even a huge Solar Burst. As told me they used it recently to silence an Email production site they had to quickly do so that they couldn't do any other way, per this book....

Duhh .....

Few people seem to recall the last huge Solar Burst we got here in the USA in the mid-1800's about the time of the Golden Spike. So history says, it completely took out most of all the at-the-time telegraph systems which all had to be rebuilt or replaced.

At any rate, can anyone here conjecture, or better still, teach me how it would be possible to create and focus an EMP pulse that could be used as described in an airborne delivery machine? What might the antenna be like?

Just curious.

Jimmie

Probably the latter, as is done around the world nowadays for VHF FM radio,
although I confidently predict someone will contradict me with stuff about
odd-order reflections changing the sense of rotation and stuff like that.
Unless the receiving antennas are circularly polarised that won't count for
much. There's a potential benefit when mobile receivers are in use, in some
cases portable receivers as well..

In the UK the term 'mixed' polarisation is used in Band II and the
broadcasters (mainly via Arqiva) don't pay extra for a specified phase
relationship, but antenna manufacturers like Alan Dick
(http://www.alandick.com/broadcast_antennas_product_004.htm) produce
mixed-polarisation and circularly-polarised versions to suit different
markets, as they would. UK terrestrial television in Bands IV/V is all
plane polarised (H from 50 main stations and V from most of the rest) at the
moment. DVB-H trials in L-Band may have used mixed (i.e. slant or
elliptical) polarisation.

Way back up the 'phone bill I posted in a thread titled 'Circular versus linear polarisation' a link to: http://downloads.bbc.co.uk/rd/pubs/reports/1970-35.pdf which you may find interesting.

The antenna would need to be paraphysical to achieve the kind of directivity gain needed to create such a field strength whilst capable of being mounted on a helicopter. Are you sure you're not out by several factors of ten in respect of the field strength?

Chris

PS: ... however, this is the right place to meet pedlars of paraphysical antennas!

Sounds like the BalUn was doing a superlative job.

Hi Owen,

What you describe (sans the problematic word latent) is specific heat capacity. And just like any capacitor, charge/heat does not increase after a source is removed. If it is not removed (which I presume was the intent of both your statements), then the specific heat capacity you describe is a design boon.

I used the term latency in the context of time, there is a delay between commencement of application of steady power to reaching substantially full operating temperature. Yes, the effect can be predicted using the material specific heat capacity, subject to the temperature variability of the ferrite characteristics.

...

Yes, but a trap if long term use is envisaged but tested only in the short term.

Gyrotron, driven by a Flux Compression Generator.

basically a very high power microwave transmitting tube at a high enough frequency where a moderate sized antenna gives a narrow beamwidth (e.g. at 10GHz, a 2 meter antenna has about a 1 degree beamwidth.. 100GHz with a 20 cm antenna does the same.) , with a HV pulse generator that uses the mechanical energy from an explosion to generate the HV high current pulse to run the tube.

Now.. 30 MV/m at a distance of say, 200 meters..

Assuming you're in the far field, so E/H = 377 ohms.. H = 30MV/m/ 377 = 0.08 MA/m. 30MV/m * 80kA/m = 2.4E12 W/m^2... that's a pretty high power density (far higher than you'd need, in this application by the way... a few tens of kW/square meter would probably do)

But, continuing on.. let's say you've got a 0.57 degree beamwidth. That's about 0.01 radian, so at 200m, the "spot" is 2 meters in diameter, or, call it 3-4 square meters.

That means the source has to put out a peak power of about 1E13 Watts.. Say the pulse is a microsecond long.. that's 1E7 joules (10 Megajoules) which isn't a lot of energy. But a terawatt peak power? That's hard to believe.

So lets move on.. Average powers of a megawatt are certainly reasonable.. Let's scale back our field to 30 kV/m (so the power density is now 2.4E6W/m^2... still 2400 times brighter than the sun)

That's a lot more realistic, and still enough to zap stuff.

2624. Re: Fishrod an�tennas - transformer and twin-lead

Source record: 12586

To put some numbers around the problem, if one had a FT240 core which has a mass of around 0.2kg, and specific heat capacity around 800J/kgK, the energy to raise the core to a Curie point of 130�C to 300�C would be 17kJ to 44kJ. If the core was well insulated (no heat loss) and dissipating say 20W, that would take 15 to 40 minutes.

Of course, one would hope that the transformers do lose heat to the environment, and that would substantially slow the rate of rise of temperature.

Experience shows that a 5 minute test of a ferrite transformer does not indicate continuous power handling capability.

Digressing slightly, but on this ferrite heat thing...

Martin questioned my article "A review of the Guanella 4:1 balun on a shared magnetic circuit" at http://www.vk1od.net/balun/gsc/index.htm . In particular, his issue was with my proposition that the extent to which these things "work" is due to flux leakage on low � cores, the lower the �, the more they resemble Guanella's balun.

Martin's inital experiments indicated that the thing did work, but on my advice he tried prototypes on high and low � cores and took thermal pictures of the things after operation. The images showed non-uniform distribution of heat in the cores which is either due to the main heat source being the conductor losses, or that magnetic flux is a significant contribution and not evenly distributed in the toroid. The flux distribution is a credible explanation for the different patterns for same winding on the different � cores.

Again, this is one of those things that lots of hams have QSLs to prove that they "work real good".

If equal horizontal and vertical components are in phase, you have linear polarization. If they're 90 degrees out of phase, you have circular polarization. If they're at some other relative phase angle, you have elliptical polarization. (Actually, linear and circular are two extreme special cases of elliptical polarization.)

This makes a big difference in how the waves behave. The polarization of a circularly polarized wave rotates 360 degrees each cycle, while the polarization of a linearly polarized wave is fixed. If you add equal vertical and horizontal fields in phase, you get a linearly polarized wave tilted 45 degrees relative to horizontal or vertical. If you rotate a linearly polarized receiving antenna in that field, you'll get a maximum when the antenna is aligned with the field, and zero when it's at right angles to the field, that is, tilted 45 degrees the other way. If, on the other hand, you add the linearly polarized vertical field to a linearly polarized horizontal field that's 90 degrees out of phase, you get a circularly polarized wave. The signal amplitude won't change at all as you rotate the linearly polarized receiving antenna. It'll stay at a constant 3 dB below the best response you got from the linearly polarized field.

If the H and V fields are added with some other phase angle, you'll get some variation as you rotate the receiving antenna, but no complete null.

... but how much damage is a pulse of 10 GHz RF going to do? The effectiveness of a nuclear EMP much to do with its very broad bandwidth (as well as its rise time).

Not that I know anything about the subject, Officer.

We are getting a little "thread drift" here but ...

When the shift to HDTV came we suddenly found that we couldn't get reliable service for most of the channels we were used to. We live in a semi-rural place and it's over 50 miles (as the crow flies) to the nearest broadcast TV antenna.

A neighbor suggested the antenna mounted amplifier (I already had a "distribution amplifier" in the basement) and it fixed us up.

Mast-head amplifiers always were appropriate for 'fringe-area' reception in the old days when there were fewer transmitters around. The dynamic range issues occur closer to transmitters, of whatever type, whose signals get into the front end. If someone puts up a TETRA (or equivalent for your country) base-station near your house you might find amplifiers a lot less effective.

Hi Owen,

This opens another topic of my study with Thermal Resistance. One paper that I have filed away that may aid you is W.E. Hord's "Recent Developments In The Average Power Capacity Of Rotary-Field Ferrite Phase Shifters." It may lack the specific application discussed here, but it covers the math and interface relationships. Sorry, but I don't have any publication details except for author/title.

Hord's work is with ferrites capable of sustaining RF power levels in multiple KW. My first experience with ferrites (ca. 1972) was with RF transmission line source/load isolation in the microwaves (the paper is S-Band), a field that is wholly alien to discussion here.

For sure. I was on the verge of returning my last analog TV because it wouldn't get one channel at all, and several others were very poor. But then I got an idea and added an attenuator at the antenna input. Problem solved -- got a great picture on all channels. The new HDTV has a better dynamic range and can put up with the strong signals, so it doesn't need the attenuator. I'm about 10 - 15 miles line of sight from urban broadcast towers. I use a commercial TV antenna in the attic.

Actually, I was thinking more like 100GHz, so the beamwidth would be
small for a reasonable sized reflector.

But, you've also identified the key thing when evaluating EMP vulnerability.

More like, put your radio in a microwave and turn it on.

60 pulses/second (in the US).. 600W average power. Figure the power density is probably in the 10 W/cm^2 rough order of magnitude, or 100kW/square meter. Peak to average ratio in a microwave oven is pretty low (3?), so thermal effects on a lossy medium will be significant.

The 30kV/m (which is achievable as described earlier, a megawatt over that 2 meter circular area) is around 24 times that. I think it's safe to say that 30kV/m sorts of fields will fry stuff, in general, pretty much independent of its resonant properties. Crumpled aluminum foil sparks pretty well, as does steel wool.

As for personnel exposure..

Yep, you'll get a burn.. probably cook your eyeballs too. Although, at 100GHz, the penetration depth is small..Might just cook your skin off like a horror movie.

I don't know what the penetration scale depth at 10 GHz is, off hand. Certainly several cm (I'd expect it to scale as sqrt(1/f), and 2.45 GHz in a microwave oven clearly penetrates 10 cm at least, or you couldn't cook a big roast at all evenly)

That's the challenge, of course.. High enough fields to cause arcs/breakdown to destroy the electronics, but low enough average power that thermal effects are minimal, so you don't kill or injure the people.

1-10 MW peak powers at pulse lengths of microseconds are pretty standard radar fare. Fire it at 1pps, and the average power will be down in the few watts area, so personnel safety isn't as big a problem. There are lots of cases of folks being exposed to fields of this magnitude accidentally, and they don't die as a rule.

There is a tale in the FCC enforcement literature about a guy working on a FM broadcast tower where he noticed sparking and smoke from his protective garments after the station manager remotely turned the transmitter on to full power.

On a smaller scale, I've accidentally killed quite a few pieces of electronics with fast HV pulses. It kind of goes with the territory when you fool with Marx banks and solid state electronics. Even fairly low powered Tesla coils will do a number on garage door openers, but I think that's because the GDOs are kind of cheap designs, with long wires hanging out of them, and it doesn't take much to kill one. That's basically discharging a 50pF cap charged to 100-200kV in a few tens of ns.

Hi Chris,

Your statement implies that a "basis" can lead to some new unique RF
phenomenon.

If EMP is co-opted for some trendy single purpose definition that
denudes the former understanding of its general (and still no less
applicable) meaning, then, yes, we have descended into opinionated
belief systems which depend upon faith.

What you infer by "basis" is that this particular pulse (with the
unstated nuclear detonation, or an e-bomb as the initiator) is somehow
different from all other pulses. No, not in the least. By whatever
"basis," there are very ordinary formulas that allow for rise time,
fall time, pulse duration, magnitude, and such artifacts as ringing
(undershoot, overshoot, crest, and the rest).

"Basis" is not another engineering term for magnitude. What was
astonishing through nuclear detonation was corralled and managed into
an e-bomb, which is nothing more remarkable than clever engineering of
shorting a capacitor. Each of the three could be cleverly induced to
give the same RF signature - what price "basis?" It happens a
trillion times a day with all the microwaves ovens on this earth.

The effects on equipment of repetitive cycles of incident electric field strength with alternating polarity, constant period and equal rise and fall times (AKA a sine wave), whether continuous or 'pulsed', are different from the effects of an incident pulse of electric field strength with a short rise time that is not broken up into harmonic cycles. The latter can induce a high voltage pulse that is wideband in the same manner as the result of a lightning strike, and this can propagate through an installation causing damage. The former cannot do that. Of course, I appreciate the difference is the spectral width of the incident 'signal'.

The example you gave was of the former type, radiation from a microwave oven, whereas I had written about the latter type. An open microwave oven may well cook a human but it won't have much effect on a power cable feeding a computer other than, perhaps, melting the insulation! A wideband pulse of electric field of sufficicient strength will damage the computer. But, evidently, you disagree ...

Richard

To see you write that the "clever engineering of shorting a capacitor"
is remotely similar to standing in front of a microwave oven is very
disappointing to say the least. You are losing your edge.

You know very well that they aren't remotely similar in the effects
produced. For one thing the "clever engineering of shorting a
capacitor" is very misleading without at least some explanation of how
different it is from simply shorting a capacitor.

Hi Tom,

EMP is a fast charge/discharge event. EMP products come in three flavors, I will only discuss the fastest. The fastest is rarely described with a risetime less than 1nS, but I have seen others bandy about the frequency of 10GHz, so we have to assume they have links to literature that claim a risetime on the order of 33pS. Be that as it may, mercury switches can switch a 1000V pulse into a 50Ohm load in 500ps. This is laboratory stuff, not armament. Armament can be engineered to perform with larger supplies as one-shot disposable switches (you don't run lab equipment to failure, new out of the box on the first application of power). Such switches are controlled access and limited sale items.

To generate this 10GHz pulse would require very, very short very, very low resistance leads; which would, of course, become part of a tuned (to 10GHz) circuit. The trigger device often employs a charge driven shorting bar. It is only a matter of capacitance and low resistance metalurgy from there.

Hi Chris,

You are mixing frequency domain with time domain descriptions. Example
repeated from above:
>a short rise time that is not broken up into harmonic cycles.

"A short rise time" is made up of an increasingly dense spectrum of
harmonic cycles. It cannot be otherwise.

>
>The example you gave was of the former type, radiation from a microwave
>oven, whereas I had written about the latter type.

You are now mixing modulation into the time domain to argue against a
frequency domain solution. Modulation, if anything, adds even more
spectral (harmonic cycle) products.

Besides, I offered you simply reduce the number of modulation cycles,
by their count, to reduce the effect to that of one cycle (of
modulation). A pulse is a modulation of one cycle (however poorly
shaped it may be, and it envelopes a pluarity of SHF cycles).

> An open microwave oven

No, not evident at all. Any "effect" is more a function of amplitude
than a failure to warm insulation:
On Tue, 6 Oct 2009 10:43:10 +0100, "christofire"
<christofire@btinternet.com> wrote:
>but how much damage is a pulse of 10 GHz RF going to do?
"How much damage" speaks specifically to that function of amplitude,

not pulse shape, not rise time, fall time, or the rest; and as you are explicit in giving a specific frequency.... The microwave oven example suitably answers this. A RADAR example does even better (and still the results, save for amplitude, are the same).

Charge here means explosive charge (accelerating the shorting bar into
the capacitor).

>It is only a matter of capacitance and low resistance
>metalurgy from there.

The capacitor is called a Marx bank (some cold-war irony there) in a
Explosively Pumped Flux Compression Generator. There are issues of
self shorting inductors wound around cylindrical explosive charges and
reams of discussion which all basically devolves to very simple and
fundamental LC with peak IR relationships.

How could it be otherwise?

That gets me to wondering...

Is my theory about RF energy being little turds that fly off an antenna
in agreement or disagreement with those particels?

I'll refresh everyone if they didn't hear it before.

RF energy consists of little packets of waste material, like little
turds, that get ejected from an antenna (as the last link in the chain
as new material flows into the antenna. This is obvious as a
characteristic of conservation of mass as well as general digestion.

These little turds leave the antenna with great velocity. While flying
through the air, they are naturally attracted to other antennas (derived
from holistic like treats like principles) and are therefore received on
other radios.

The result and characteristics of this process are that unless
transmissions match reception, which is almost impossible, the little
turds accumulate on our antennas, and over time result in crappy
performance.

One must expand on this to include impedance matching ointments such
as Preparation H (and the lowering of transmission line restriction
losses with Ex-Lax). Can it be said that diamagnetism is like a
greasy lube job for propagation?

If they are to be circularly polarized, they will need a corriolis
evacuation.

If you are talking about a balun made with an electrical half wave of coax, you may be hard put to observe the difference between using 50 ohm or 25 ohm line. If the load was an ideal resistor, using the 'matched' Zo gives least loss and best bandwidth, but on a narrowband antenna, the balun bandwidth is less an issue, and may even compensate the antenna (depending on the chosen Zo).

The OP's application to a quarter wave line is sensitive to Zo though, and it works fine, but it is quite important to bond the shields effectively at both ends of the line.

Ian,

The DK7ZB match (http://www.mydarc.de/dk7zb/images/match-12+28.gif) is interesting. Ideally, the transformation sections (the inside of the coax TL) are an electrical quarter wave, and the balun (the TL formed by the outside of the coaxes in parallel and the boom etc) is a quarter wave.

I would be surprised if constructions typically shown achieve that optimisation, due at least to the use of solid PE dielectric inside the line, and a air / vinyl dilectric outside.

The construction at http://www.mydarc.de/dk7zb/DK7ZB-Match/Schleife_Isolation.jpg is quite complex, containing what might be seen as as an electrical quarter wave transformer and the balun formed of a U shaped stub of physical length 0.5*0.25*0.66=0.08 wavelengths shunting one side of the DE, but this stub lies with its hot side against the cold boom forming another o/c TL element. If the balun shunts the DE with a high impedance, it will be due to not just the loop length, nor just the s/c stub length, but parallel resonance with the boom / half loop o/c stub.

If that is the case, the construction is not simply explained by the first diagram that I referenced above.

I am not suggesting that this implementation doesn't work, but that there are design parameters beyond those implied by the electrical circuit given.

Thoughts?

Owen

that makes sense. It may retreat to a familiar
ritual, like checking equipment. But it may also
turn its attention outward, the researchers argue,
and notice, say, a pattern in animal tracks that
was previously hidden. The urge to find a
coherent pattern makes it more likely that
the brain will find one."

Lest Art or Stefan stumble into this as vindication, the easy chair is
their wild notions, we are the hikers that are left with the
nonsensical application who then gain heightened perception. Students
who were subjected to a story by Kafka (and anyone who has read
through a tortured thread started by Art has experienced a lifetime's
exposure to Kafka poisoning) were then tested in their ability to
discover hidden patterns:

"The fact that the group who read the absurd story
identified more letter strings suggests that they were
more motivated to look for patterns than the others,"
Dr. Heine said. "And the fact that they were more
accurate means, we think, that theyï¿½re forming new
patterns they wouldnï¿½t be able to form otherwise."

> It works well.

It has to work well.

Suppose first that you connect a load with impedance Z to the far end of a quarter wave transmission line of 25 ohm surge impedance. At the near end of the quarter wave transmission line this will look like 25^2/Z ohms, or 625/Z ohms.

Now start over, but instead of the load with impedance Z suppose you have two identical loads, each of impedance 2*Z, which if they had been connected in parallel would have had an impedance Z. Take two different quarter wave transmission lines, each of surge impedance 50 ohms, and connect the two loads (separately) to the far ends of the two transmission lines. At the near ends of each of the transmission lines this will look like 50^2/(2*Z) ohms, which simplifies to 1250/Z ohms. Connect the near ends of the two transmission lines in parallel. You will then see 625/Z ohms, the same as you saw with the Z ohm load at the end of the quarter wave 25 ohm line.

By symmetry the voltages across, and the currents through, the two 2*Z ohm loads have to be the same. So nothing will change if they are connected in parallel. Do that and you will have a single Z ohm load at the far end of the two paralleled quarter wave 50 ohms lines.

There are two separate issues here. The impedance transformation with
paralleled coax is no problem (which answers the original question).

The other issue is the way the feedline is looped to form a balun... or so it is claimed. Like you, I am quite dubious about that.

It is highly reminiscent of a system used 20-30 years ago on the yagis made by Antennes Tonna (F9FT). The coax exited vertically downward from the feedpoint, and the instructions were to leave a quarter-wavelength hanging loop before the coax came back up to the boom. There was no electrical connection to the boom at this point - the coax was taped tightly down, and then continued along the boom as normal.

The quarter-wavelength loop was about 19in for 144MHz; but for 432MHz it should only have been one-third of that, which was an impossibly tight bend for heavy low-loss coax.

No doubt this arrangement would *somewhat* increase the common-mode impedance at the feedpoint, and thus act as a sort of balun, but it never seemed like a properly engineered solution. Many people replaced it with a home-made sleeve (bazooka) balun, and eventually the Tonna company did the same (though again, only sort of).

I completely agree that the velocity factor for the common-mode current on the outside of the coax will be different from the velocity factor inside the cable. This applies to both single and paralleled cable. Once again this makes a "quarter-wave" loop a less than satisfactory solution for a balun.

50MHz is much easier. For that band I have built several yagis using paralleled 75-ohm satellite TV coax to match a nominal 28-ohm feedpoint to 50 ohms [1]. An electrical quarter-wavelength is about 1.0m so there is no problem about coiling the paralleled coax to make a reasonably effective choke balun (the problem with velocity factors does not arise because the choking impedance is predominantly inductive). First tape the two cables together along their entire length, and then coil them into three turns.

However, the effect of any choke balun can be spoiled by the capacitance between the coax shield and the boom, which appears in parallel with only one side of the feedpoint. To minimise this effect, the entire coil should be spaced away from the boom by a *much* wider insulating gap than DK7ZB recommends. If I'm feeling cautious, I sometimes add a few ferrite beads at the start of the main 50 ohm feedline.

[1] All credit to DK7ZB for making the point that it's much easier to design high-performance yagis with a feedpoint impedance in the region of 25-30ohms. He feels that increasing the feedpoint impedance to 50 ohms (eg by adding a closely-spaced first director) makes optimization more difficult, especially when 28 ohms is such an easy impedance to match. But that is yet another separate issue...

Hello, Roy, and all. The trade-off here is that while putting a pad (attenuator) in front of the amplifier certainly results in a lower signal level at the amplifier output being presented to the down-stream components, the noise figure of the pad+amp cascade is increased by the attenuator loss (assuming a matched (e.g. 50 or 75 ohms)) pad. If the pad is placed at the amplifier output the noise figure is preserved but the dynamic range (usually specified in terms of a third-order intercept point) of the cascade is degraded. Noise figure and intercept points of RF distribution system amplifiers used in a shipboard environment have always been of vital interest to the USN. Sincerely, and 73s from N4GGO,

One might want to distinguish between EMP from, e.g. a nuclear device,
which is a fast pulse (the rise time of which is fundamentally limited
by the size of the fireball.. EM energy from the far side takes longer
to get to you than the near side)

AND

EM weapons designed to create damage similar to that from EMP.

Those are usually high peak power microwave sources with moderately long
pulses, designed to put enough energy into the victim to cause the damage.

There is also, the much talked about and demonstrated broadband pulse
generator schemes... some sort of fast discharge into a broadband
antenna (often a bowtie).. You see these demonstrated as built into an
attache case. Put the briefcase EMP generator next to the victim
electronics, trigger the bang, look! dead PC.

This is typically a few hundred joules with a low inductance pulse cap
charged to a few kV or 10s of kV, discharging through a triggered spark
gap.

Ground Pulse Radar does a very similar thing (with better calibration, lower powers, etc.)

This thing is used to encourage funding of countermeasures or funding of "bigger and better" versions, particularly in front of folks who don't understand things like inverse square law.

Erwin Marx of the eponymous Marx bank has no connection to the Marx of political theory. Marx published his papers describing the design of his impulse generator in the teens or twenties, as I recall.

Flux compression generators are different. I suppose one could use a FCG to charge a Marx bank, which would self erect, but I don't know that would buy much in a weapons context.

The discharge time of a Marx is limited by the stage capacitance/inductance. The fact that you stack a bunch in series helps reduce the C, but the series L and R exactly counteracts it. The big advantage is that once you get outside the generator, higher voltage lets you have higher di/dt on the rest of the circuit, but that presumes the rise time of the Marx is faster than the limit imposed by the load R/L/C.

There are better ways to make very fast high voltage pulses, if that's your goal. Fruengel's books on "pulse discharge" provide a plethora of ideas.

Ultimately, the limit is the propagation speed in the conductors (so schemes using transmission lines are popular: Blumlein published one in the 40s(?) that's used a lot)

Ya know, that don't sound like a half bad idea. I might just
have to do that some day. :/ I have the usual lawn type chairs,
but a thick padded recliner sounds like the cats ass.
Vinyl of course, due to the usual fowl fallout I'd probably encounter.
:/
Of course I'd then be motivated to add an end table for my radio,
small fridge to keep adult beverages, snacks, etc. Maybe a
flat screen so I can watch Wonder Woman and Lonesome Dove.
I wonder how a lost hiker would deal with something like that?
Would they bark at the moon? Or just sit down and drink all
my adult beverages while watching reruns of Lost in Space?
Only The Shadow and young Will Robinson know for sure.
****
This would be a good way to avoid ever getting lost. Just sit down in the
chair, and another hiker is CERTAIN to amble along to ask you what you are
doing!

I should have explained that looking at the reference picture, and
considering the insulation between cable and boom, I made the assumption
that the braid nearest the boom was connected to the DE, and other braid
end was effectively grounded.

It may actually be the other way round.

In any event, the physical construction is not IMHO well approximated by
the electrical equivalent shown, nor the description "This line is a
simplified coaxial sleeve balun to avoid sleeve-waves on the braid of the
cable running to the station". Making this balun adequately effective may
involve more than just cutting the line sections to the dimensions
indicated.

Owen.

Hi Jim,

Actually, a nuclear detonation propagates three forms of EMP. We both
discussed the fastest which correlates to discussions ongoing here in
the 1GHz and higher spectrum.

I will leave it to Art to wonder of the mysteries of an atom bomb
pushing aside magnetic field lines (what? no equilibrium?) for the
slowest pulse. For purposes of Focusing this EMP pulse he has his
shoebox sized 160M dipole/reflector technology to fall back on.
Perhaps he might consider a nuclear hand grenade. I would love to see
a youtube video of him pulling that pin and tossing it into the
reflector.

Absolutely, and designing an effective, efficient, reproduceable matching
arrangement is an essential part of system design.

Whilst I have reservations about the design pics etc referenced, the
fundamentals of the Yagi itself look good, and with an impoved matching /
balun element, it looks like a practical high performance antenna. They
are certainly becoming more popular in this part of the world where most
home brew designs are DL6WU based (for good reasons, but peformance isn't
the principle goal).

An improved design could persue a more reproduceable balun that had an
adequately high shunt impedance on one side of the DE, or better, a
symmetric balun, and the shunt impedance was tuned out as part of the DE
tuning adjustment. The latter, if done properly, should result in more
symmetric current distribution on the DE, and pattern closer to that
modelled.

On that point, I am often somewhat amused at the out of hand dismissal of
gamma matches because of pattern distortion, and recommendation of
asymmetric baluns in their place. Symmetric baluns are just not very
popular with hams on VHF and UHF.

Owen

Interesting that you are among a group that uses the DL6WU designs.
They were very good for their day, but the K1FOs had better all over
performance, especially regarding wet weather degradation. And they
were around 20 years ago.

The T match combined with what I've always thought of as his "4 element
launcher" is pretty much bulletproof. I think he may have been the
first one to have the first director very tight to the DE, which had
very desirable effects.

All you had to do was splice the first 4 elements from one of his
designs onto a well designed group of directors and you had a great
antenna. OK, not quite that simple, but a good place to start.

And I agree on the gamma. I like the T, but have never been able to see
any real issues from a gamma. As a disclaimer, I only use gammas on 6m.

Rick or anyone else for that matter.

Can anyone suggest a strategy for reasonably safe operation of a
station when lightning is actually present in the area. The stations
located at the weather service offices are used to receive real time
weather reports from AROs. If they go off the air during lightning
events the whole network becomes useless to the weather service.
Television and radio stations continue to operate even after direct
strikes to their antennas so it must be possible to provide protection
that does not involve shutting down when lightning is present. Can
anyone draw me a written sketch of how that gets done so that I can
make a more knowledgeable decision on whether or not to try to
replicate the technique.

The attenuation of an attenuator at the input of an amplifier adds directly to the noise figure (e.g., a 20 dB pad increases the noise figure by 20 dB), but the dynamic range remains the same. The dynamic range is the ratio of the largest to smallest signal a receiver can handle with acceptable performance, often defined as the ratio of the third order intercept to the noise floor, which doesn't change when you add an attenuator. For example, just picking some numbers, suppose the noise floor is -100 dBm and the intercept 0 dBm, for a dynamic range of 100 dB. Add a 20 dB attenuator to the input. Now a signal (at the input of the attenuator) of -80 dBm will be at the noise floor, and +20 dBm at the third order intercept. The dynamic range is still 100 dB, just shifted 20 dB higher. Many of the finest receivers have switchable attenuators at the front end to increase the maximum signal handling capability.

In any case, there's no real alternative to an attenuator if the signal to a TV set is too large for it to handle.

Hi Tom. In general, remember that all lightning strike issues, from cloud to ground or .. ground to cloud, depending on how things develop focus on on thing. The radio wave which is produced by the affair is trying to distribute itself over the surface of the earth in the area of the strike point.

Recall that radio waves travel over the surface of the conductor involved. Thus, for example, the tower, pole, tree, building or whatever is the strike point is a conductor, good or bad, which is going to be used to carry the wave to the surface of the earth at that point. Then the wave expects to travel outward on the surface of the earth away from the focal point of the conductor until the energy of the wave is used up.

OK, think this way. A more or less usual lower frequency tower for an AM station in the 500-1650Khz band is actually built so that the metal tower is directly grounded at the earth surface. At the 1Mhz point, the tower height for a quarter wave tower is around 250 feet high. Actually, at the bottom of the tower there is usually a metal plate that spreads out over the surface of the earth that is tied to the tower bottom, (Legs?). As well, for transmitter antenna purposes, there are also a more or less standard 120 copper wires that go out like spokes in a wagon wheel at or just below the surface of the earth there too.

That means, very much surely, any lightning strike which hits that tower has a WONDERFUL way to go to the surface of the earth, then spread out over the surface away from the tower. The trick at this point is to keep the lightning strike from going on into the radio station from there. On a quarter wave length high tower, the conventional way to couple the transmitter to the tower is at the base to move out a little way from the tower, go up a little way with a separate wire, then couple the feed line to the tower via what is called a shunt feed system. It typically has a capacitor in series with the coaxial cable center conductor. And .. in all cases, the cable that goes back to the station will be close to or .. even in some cases under the surface of the earth for that run.

The lightning protector will be out at the tower and will arc or flash the lightning bolt that might go down the feed line to the station so that it shorts the feed line for that split second for SURE to the earth and that collection of the metal plates and radial wires that make SURE the strike out over the surface of the earth and NOT back toward the station. As well, there is usually another lightning protector which does a similar job back where the feed line goes into the station as well.

Using this technique, sure for a split second the station signal is shorted to ground when the strike is there. But it does NOT affect the station.

Now .. fast forward to VHF TV, FM stations and HF shortwave stations. For towers for FM or TV stations, they may be MUCH higher, But the feed lines for the antenna or antennas on them are brought down the tower to GROUND level. There they are also put through lightning protector devices that do the same stunt of shunting the strike to the EARTH at the bottom of the tower. Then, the feed lines are send back to the station at, again, a same low level which protects them from carrying in the strike back to the station, as above.

Variations of this sort of design are also present in on-building antenna systems that are done right to protect the equipment from strikes. One way or another the design ALWAYS should provide a VERY GOOD electrical path from the antenna to the earth, that is designed to have enough metal SURFACE to get the hit down to the earth without burning the conductor up. And again, this travels on the SURFACE of the wire, metal strip, pole or whatever.

Bottom line. You always create a really good metal surface conductor that shunts things to the earth. And connect the feed line(s) for the antenna so that they are isolated from this good path to ground by bonding the shielding to the earth bound system, while providing a lightning protector to guarantee that the hit will pop to the ground bound side on a hit, while positioning the

feed line so that it is a much less attractive path for the hit to go in to take down the equipment at or in the building.

There are other things that are also of importance to a radio operation for protection from power line connected strikes, as well as overhead phone line strikes and copper wire cable system connections too. But, in general, the same details as above are in place for them too.

My HF site gets hit at least two or three times directly every year. I operate right through thunderstorms, whatever in contests and have for decades now on 40 and 80 meter CW. With additional protection for the equipment this site is up 24X7 and hasn't lost a single radio, computer, modem, or ANYTHING for over 30 years now, though I also know enough to use isolation transformers and linear power supply computer systems, plus very carefully planned relay rack RF ground and surge protection techniques that do *NOT* use switching power supply CD voltage operations for computers and so on.

Got to polyphaser's web site, read their white papers and contact them.
Between them and Trans-Tector (they recently merged), they do antennas and
power lines for things like air traffic control centers.

Geoff.

Here are the two ways.

1. Provocation of lightning strikes, or
2. Eliminating of lightning strikes.

The instalation are the same only "tipping" is different. The blunt
provocate and the sharp eliminate.
Which is better I do not know.

>> Owen
>

The most that anyone can claim for a balun is that it "helps to promote" a symmetric current distribution on the DE. Current baluns are quite successful in enforcing equal and opposite currents at the feedpoint itself, but that is only one of three requirements for a symmetric current distribution over the entire DE. The other two are symmetry in the DE's physical structure and symmetry in its environment, and the balun can do nothing to 'fix' those.

I'm not quite sure what you mean by "symmetric balun". If you look closely enough, no balun can be completely symmetric in every detail... but certainly some baluns and feed arrangements are much more symmetrical than others. Some help to promote symmetry, while others are "not part of the solution, but part of the problem".

I'd place the gamma match firmly in that second category. Far from promoting a symmetrical current distribution in the DE, by its one-sided physical structure it *creates* electrical asymmetry. An asymmetrical current distribution at the feedpoint implies that there will be an 'I3'

common-mode current on the feedline, and the gamma match also provides a hard-wired connection to launch this current onto the outside of the coax (and usually onto the metal boom as well).

As you may gather, I don't like gamma matches on principle! That has been confirmed by practical experience with a gamma-matched yagi for 50MHz (which I bought as a kit, foolishly thinking it would save time). RFI on both transmitting and receiving was severe, but cleared up remarkably when the DE was rebuilt to use centre feed through a choke balun. The improvement was simply due to blocking the common-mode current that the gamma match had been launching onto the feedline, boom, mast, rotator cable...

Tom wrote, replying to Owen:

DL6WU's yagi development pre-dates K1FO's work, but the latter was influenced by earlier development work by Tom Kirby, W1EJ. We also have to remember this was before the modern era of instant communication; people in different countries often worked for years on very similar projects with no idea of each other's existence.

Both DL6WU and K1FO designed 'families' of long yagis based on the same "launcher" structure (the first 4-6 elements) followed by a suitable array of directors. Also, both of them used a very close-spaced 1st director to increase the feedpoint impedance of the DE - it had been done before by cut-and-try, but DL6WU was probably the first to do this *knowingly* and explain why. (As an aside, G0KSC's new loop feed is doing essentially the same; the typical width of the loop is very similar to the typical spacing of a close-spaced 1st director.)

>And I agree on the gamma. I like the T, but have never been able to

Not really.

For examples, over a given r-f bandwidth:

- Radiation pattern throughout the free-space radiation sphere?
- Free-space gain with respect to an isotropic radiator (dBi) or a matched, 1/2-wave dipole (dBd)?

Note that any particular r-f termination may have low feedpoint VSWR over a considerable bandwidth, for some reference impedance value -- but that does not necessarily make it a useful antenna (think: dummy load).

In my previous post in this thread I asked about the gain and pattern of this mesh antenna. Hopefully the inventor will respond when he is able.

But being curious and not wanting to wait, I went back to his previous thread about small antennas, and modeled what he posted there -- just to learn what NEC would show for those parameters.

The results are given in the link below.

The h-plane azimuth gain of this mesh antenna is far from uniform, and its 0.0134 + j85.45 ohm feedpoint impedance is very unfriendly -- though the frequency is centered in Art's stated VSWR bandwidth.

Even if this feedpoint Z was perfectly matched there to a 72 ohm balanced transmission line, this mesh antenna would still be a poor radiator compared to a 1/2-wave dipole.

So then, based on all you've learned from Art, why don't you give a brief description of an antenna based on Art's principles. Please give some dimensions.

Evolved? Never.
Revolved (Corriolis)? Perhaps.
Devolved? Almost certainly.
According to Art, himself, he would a levitationist.

What would account for his astonishing description?
"Thus we have three types of Leptons
each able to produce one of the primary colours,
red, green or yellow."

I wonder what happened to Blue (or ultra blue for that matter, or even X-ray). It might astonish Art (belay my last, that isn't going to happen) that red and green combined ARE yellow (how does that not happen in Art's side of reality?). Even Newton understood this. Of course, this may be Art's spit-on-Newton week.

Hi all

I'm looking to purchase an antenna analyser and after reviewing the various products on offer and viewing reviews at eham I'm leaning towards the AIM4170 analyzer.
The eham reviews seem very positive therefore I'm keen to hear the experience of others in this group regarding this product and perhaps some of its short comings.
I previously ask for comments on the MFJ-269 analyser and found comments valuable.

Thanks for your time.

Hi Peter,

I bought an AIM4170 about 10 months ago, and have absolutely no regrets.
It does everything as advertised, and is very easy to use. Apart from
all the good comments on eham.net, the unit doesn't eat batteries,
doesn't suffer from broadcast station interference, and doesn't burn out
if you set switches in the wrong order.

Other things I like about the 4170:
~~~~~~~~~~~~~~~~~~~~~~~~~~
-- It's easy to measure antenna feedpoint impedances (as well as
feedline input impedances).

-- It provides two sets of Smith charts.

-- It's easy to keep screen shots of your measurements, so you can refer
back to them later -- no more scribbling numbers on scraps of paper.
~~~~~~~~~~~~~~~~~~~~~~~~~~

You can't do those things with legacy analyzers.

Another benefit of the 4170 is that you can operate it remotely. This
means that you can leave the unit in the shack, then go out into the
yard with a notebook PC and control the 4170 from the notebook. Thus you
can make your antenna adjustments without having to trek back into the
house each time you make a change. Full details here:

<http://homepage.ntlworld.com/wadei/AIM4170/Remote%20AIM%20Control%20HOWT
O%20-%20090106.pdf>

The only snag with the 4170 is that the upper frequency limit is 170MHz, but that doesn't bother me.

If you have more questions, take a look at the 4170 forum:

<http://aim4150.proboards.com/index.cgi?board=analyzer>

I agonized for a long time over the price (and watched it getting more and more expensive as the GB pound slumped against the US$!). In the end, however, I figured that the 4170 was only a few tens of dollars more expensive than the legacy analyzers, and you get so much more. Go for it!

I am trying to find out how far an open stub, dual band, two meter and seventy centimeter J-pole needs to be from a parallel metal support mast on which it is side mounted to avoid detuning the antenna. I'm not concerned about the effect on the radiation pattern as I can mount the antenna on the side of the mast towards the area I'm trying to cover. I have to build brackets to accomplish this mounting and I would like to avoid building multiple sets of them just to test for clearance. If anyone has the requisite skills and tools I would appreciate any information that can be readily found by modeling this antenna in proximity to a metal support mast consisting of four inch aluminum tube. I have two AB-952 masts on which to mount six antennas. Three of them will be two meter omnidirectional antennas. Since we need two limit interaction and interference between the three two meter stations We will be mounting one of these at the top of one mast, one a third of the way up the second mast, and the third two thirds of the way up the first mast. Both masts will be deployed with extension kits so they will be fifty feet in total height.

In truth I just do not have the skills or the time to develop them to do this so any help would be greatly appreciated. This is for a public service event that is now only two weeks away.

I'm not a modeler. However, I did investigate this experimentally a
few years ago, although not with 4-inch aluminum mast. I used a 10-
foot section of one-inch galvanized mast. The tested j-pole was a 2m
copper pipe version, hanging vertically in the open, suspended by a
piece of line.

On transmit, I tuned to a simplex channel, keyed up, ID'ed and noted a
small amount of reflected power. I locked the key and slowly moved
the section of mast toward the antenna. I had to get within one and
one-half inches (1.5") before the reflected power increased.

On receive, I tuned to a repeater with a ragchew in progress and
opened the squelch. I inserted a switchable attenuator in line with
the radio and set the attenuator to the crappiest signal I could copy
-- one dB away from unintelligible. Enter the mast section, and once
again, I had to get within an inch and a half to lose the
conversation.

The direction from which I approached the antenna didn't seem to
matter, but I didn't do any real measurements of pattern distortion.

I hope this helps you.

Sal

Ian

Thanks for the reply. It appears to be the stand out performer for the
price, but as you say the only limitation is the 170Mhz upper limit,
something I can live with.

Regards

I never tried it as close as Sal but It did mount one that stood off
about 2 ft from the tower with no discernible problems. I was also in
on making a J antenna where the tower was part of the antenna.

It's $500-$600, a bit more than the average ham would want to spend, unless you are into serious contesting or DX chasing. Myself, I would love to have one, but for my needs the MFJ at $225 has worked for years. In the future, I may get more real estate, and the AIM4170 may be just the ticket.

Or into antenna tinkering for its own sake.

For myself, I have the TAPR/TenTec VNA, because it was a better fit to my particular needs, but the 4170 is a nice, useful piece of gear.

It's hard to predict what the "average ham" would be interested in, in any case..

2712. Ground antenna?

Was talking with someone the other day and mentioned that I had just grounded the antenna (the mast, actually) to protect against lightning strikes, and they said that was not such a good idea because lightning is more likely to strike a path that goes straight to ground. Now I am not sure what to do. Anyone have any input on this topic? Ideas are gratefully received...

Thanks,

Dave

Hi Dave,

Did they happen to mention what a great deal it was for that lightning
to go directly to your radio instead?

I suppose their next argument is that lightning won't strike an
"insulated" antenna....

One reason for lightning conductors (and for grounding elevated
conductors, like radio antennas) is that it helps to stop a high
electrostatic charge from accumulating in the air immediately above
them. The intention is to PREVENT a direct lightning strike, rather than
conduct a strike to ground. Of course, if a direct strike DOES occur, an
antenna (and even a stout lightning conductor) may be seriously damaged.

If you ground the antenna and the tower/mast the lightning will flow to the ground source of least resistance. ie: It will flow down the mast/tower to ground and not into your house, at least that's the theory.

The only problem with that is that the charge is so quickly
replenished
that I think trying to bleed off the charge is a waste of time.
Note the "brush" type conductors that supposedly dissipate the
charge to avoid a strike. They don't really work too well, and when
they do get struck, often you have blobs of molten metal flying
about.
The way I see it, the only way to really prevent a strike, and even
then I think it's iffy, is to provide a shape that does not stream
well.
And then have a lightning rod which does stream well to take the
strike vs the object that does not stream well.
IE: a rounded ball on top of a mast does not stream as well as
a sharp tip. This is why most flag poles have a ball on top.
To reduce the likelihood of streaming. And even those can still be
struck under some conditions. So I think trying to avoid a strike
using such methods is more wishful thinking than anything.
I look at it in a different way. I expect it to be struck, and it will
if it's any decent amount of distance above the surrounding objects.
It might take 6 months, or it might take 6 years, but it will be
struck some day. Count on it.
A strike does not know where it's going to hit until about the
last 150 yards or so. Then the streamers from the ground
are all pointing towards the down leader trying to entice it.
Usually the strongest streamer in the area will attract the
strike. And even that is never a sure thing. :/
So the best way to deal with lightning is to expect it to
strike sooner or later, and to provide the most efficient
path to ground when it happens.
A well grounded mast DOES NOT attract lightning any
better than a non grounded mast at the same location.
That's horse caca, and the OP can tell his friend I said so.

They will stream the same, and I consider the chances
of a direct strike about equal.
It's when you actually take a strike is when the differences
in grounding show up.
The well grounded mast will take the charge to ground
in an orderly military manner, and in most cases no
damage will occur.
The non grounded mast does not provide an orderly
path to ground, so the strike takes whatever path
has the least resistance. And even that path is likely
to be fairly high resistance and fireworks are likely
to occur. Houston, we have a problem.. :/
The OP did the proper thing by grounding his mast.
If properly grounded, if he does take a strike, the
mast will direct the charge to ground and little
damage should occur. This does not mean you
want a radio hooked up though. That takes extra
measures like suppressors, ground window, star
grounding, etc..
But at least he won't have to worry about burning the
house down.
I've had my mast directly struck more than once, and
I had no damage at all. Period. But my feed lines
were all grounded to my bulkhead outside the shack.
I don't leave them connected as I use no suppressors.
Two of those strikes were with me sitting in this chair
15 feet away from the base of the mast.
You can actually hear the difference between a strike
to a well grounded mast, and a strike to a poorly
grounded object.
The strike to the well grounded mast will be very quiet.
Just an arc sound like throwing a light bulb on the ground.
A strike to something poorly grounded like say a tree
will be much louder. More like a crack from a shotgun. :(
This is not to be confused with the overhead sonic boom
which both types of strikes will make. I'm just talking
about the local sound.
Anyway, that's my $12.47 worth from someone that lives
in lightning country and has taken multiple direct strikes
though the years.
If the OP wants some good lightning info, try searching for
Gary Coffman and lightning on google. I don't know if his
past posts are still archived, but they should be.
He had a lot of good posts on various aspects of lightning
protection.

Like many things, "it depends".. what else is near the antenna? From an electric field standpoint, whether it's actually physically connected to the ground isn't all that important. It's that it's a conductor sticking up, and that causes the field to change. As the surrounding E-field changes over a time span of milliseconds, a mast connected to the ground vs isolated will have a slightly different voltage distribution over time, but over long times, it's not much different.

Source record: 12489

You'll have better isolation between systems if you mount all three 2M antennas on the same mast, directly above/below each other. I'll recommend 19" spacing off the pole. Mounting one quarter-wave away from the reflector is one of the easiest pattern changes to model; it gives a nice cardioid pattern on 2M. The UHF side of the J-pole antenna will therefore be 3/4 wavelength from the reflector and the pattern on 440 will have three lobes, much like a clover leaf.

I suggest using 1/2" CPVC Schedule 40 water pipe for both the vertical support and the arms at top and bottom. That stuff is cheap, easy to cut, and glues together very quickly - don't make any assembly mistakes! Put a "T" fitting at the bottom to let both the coaxes and residual water vapor drop out of the radome assembly.

2721. Antenna Pattern: Carolina Windom

Newsgroup: rec.radio.amateur.antenna
Date: 2009-10-15 20:38:52 UTC
From: rikoski@earthlink.net.invalid
Message-ID: <wLLBm.21291$eJ4.3143@newsfe07.iad>
Source record: 12482

I am installing a Carolina Windom Short 80 and am not sure which way to orient it.

The company which sells the antenna says that because the antenna has a vertical section which radiates; the antenna is omni-directional.

But others say that it radiates best in the direction of the ends.

Some disagree saying that a dipole is a dipole and so its antenna pattern would be optimally broadside to the antenna.

Since the antenna is not center-fed; if it were a dipole the lobes along the longer section would produce more signal; is that the case here.

Is this a good antenna or just so much bs?

Thanks.

See for yourself.

http://www.radioworks.com/ccwpat.html

An OCF has a distinctly different radiation pattern from
a dipole on certain frequencies. The vertical radiating
section of the Carolina Windom modifies the horizontal
radiation pattern.

That should be the end of it, then.

>But others say that it radiates best in the direction of the ends.

Amusing but false.

>Some disagree saying that a dipole is a dipole and so its antenna
>pattern would be optimally broadside to the antenna.

Possibly so, if the company who sells the antenna is wrong. Or
possibly so, if the user who bought the antenna from the company
doesn't follow installation instructions which lead to a vertical
section that radiates.

>Since the antenna is not center-fed; if it were a dipole the lobes along
>the longer section would produce more signal; is that the case here.

Amusing but false.

>Is this a good antenna or just so much bs?

Many users are satisfied. If they were to replace it tomorrow with a
design that was roughly the same over-all length, with the same
over-all match, then it they would report no differences could be
observed.

The only consideration that may fail in this proposed substitution
would be in the vertical section that radiates. The significance of
that polarization could be high, especially if the orientation of the
horizontal sections are not particularly well suited to your intended
propagation path.

In some points of the compass, your windom may exhibit interesting
polarization diversity that comes as a happy surprise; at other points
of the compass, you may need this diversity, and it isn't there
bringing a brooding disappointment. Such oddities spread over the
population of users make blood enemies and faithful converts.

If it *were* a half-wavelength dipole, I don't believe that the
direction or strength of the lobes would depend on the point at which
it were fed... center, off-center, or end (as in a Zepp).

This antenna doesn't look like a simple dipole to me. It appears to
be a combination of a doublet/dipole with the ends folded back, and a
vertical section which is deliberately designed to radiate.

The radiation pattern is going to vary, between the horizontally-
polarized component (from the flat-top and folded-back sections) and
the vertically-polarized component (from the vertical radiator between
the matching unit and the line isolator).

Horizontally-polarized radiation from the flat-top section is (I
think) going to be primarily off to the sides (perpendicular to the
wire) when the antenna is used on 80 meters, and probably on 20 meters
as well (due to the presence of the resonator stubs). On other bands
it'll be a more complex pattern, with multiple lobes. I'd expect a
null directly off of each end, on all bands.

Vertically-polarized radiation will be near-omnidirectional, and will
tend to fill in the horizontally-polarized nulls off of the end (and
the inter-lobe nulls in other directions on other bands).

The angles of maximum radiation for horizontal and vertical components
of the signal will almost certainly be different.

In short, it's going to have a complex radiation pattern which will
vary both horizontally and vertically, and will differ from one band
to the next.

>Is this a good antenna or just so much bs?

Haven't used it myself, and so I can't say for sure.

Based on its design and what I expect its radiation pattern to be, I'd guess that it's a decent overall performer, with fewer "dead spots" than a dedicated half-wavelength dipole, slightly lower gain in some directions, possibly better DX performance than a low-mounted dipole (due to vertically-polarized radiation from the vertical section) but possibly more prone to pick up close-in manmade noise (also due to the presence of the vertical section).

I am not sure what the short 80 is. I have a home built one that is up
about 50 feet and installed as flat across the top as two end supports and a
middle support will let it be. It is about 80 feet on one side and 40 feet
on the other side. The coax drops 20 feet down from the 4:1 balun to the
current choke.

It seems to work fine for me on 80 meters, the only band I normally work
with it. I have an 80 meter dipole up about 40 feet on one end and 20 feet
on the other end at right angles to it. In just about all cases the OCF is
beter than the 80 meter dipole. Only problem is when I run an amplifier the
4:1 balun overheats and the swr goes way high when I run more than about 700
watts ssb. The balun is rated for 1.5 KW.
When I had it fed with rg8X and a low power balun without the lower current
choke I could not tell much differance. I was only running 100 watts then
as I did not have an amplifier. There did seem to be some rf in the shack as
the computer speakers would make noise, but not with the current choke in
the line with the new antenna. Both antennas were ran to a 5 way antenna
switch just inside the window I was passing the coax through. The shack is
in a walkout basement and the switch has a wire ran outside to a ground rod
and that rod is also connected to another rod about 10 feet away and also to
the house ground rod about 10 feet in another direction.
With the choke and larger rg8 coax there does not seem to be any rf in the
computer speakers.

It seems to work well in all directions. I don't know if it is because of
the vertical section or just because it is only 50 feet up.
The lower 80 meter dipole seems not to be very directional either.

Actually only partially true. Think if two parallel resistors or
inductors. The current will be divided between the two. If only 1%
flows to the house, it could be very damaging.

There's no single answer because, as Cecil said, the response changes markedly with frequency.

Maximum radiation will be broadside at frequencies where it is a half-wave, and it will progressively develop multiple lobes and nulls as the frequency is increased.

The common-mode current on the "vertical radiator" tends to fill in some of those nulls, but its contribution is also very frequency-dependent.

Here's an example of the difference that the "vertical radiator" makes to a 132ft OCF dipole on 20m - one of the bands where it has most effect. Red trace is the azimuth response at 10 degrees elevation without the vertical radiator; the blue trace is with it:

Hi Steve,

Thanks for the azimuth plot. This was just what I was looking for.

I am on a sand dune above Lake Michigan 32 miles east southeast of the Sears Tower.

The antenna that I am writing about is the Radio Works 80 Special with 41' and 25' element lengths. The radiating coax is 10' strapped to a fiberglass mast. The dipole feedpoint is 30' above the sand and about 90' above Lake Michigan across the road. It is broadside to due north.

I get a lot of contacts from Georgia, Texas and the US northwest but nothing from Europe, Japan or Australia.

I work 20m ssb primarily and so have cut and put up a 3/2 wavelength centerfed dipole; slightly different location but same orientation with an aluminum mast. Similar performance on 20. With the Palstar tuner; it loads on 40.

My choices come down to keeping the Carolina Windom up, taking it down or re-orienting (But I am squeezed by 7200v powerlines and large oak trees in a terminal forest.).

It would be useful to have azimuth plots for 40 and 80 for this antenna; if for nothing else than a starting point.

Thoughts?

actually it does. both the ieee and cigre have been using lightning
statistics data collected mostly from tall masts for many years.
There are well known formulas used to calculate the number of strokes
to a pole or power line, both include the height, and as height
increases so does the number of strokes to the object. The height
also skews the current distribution with higher structures more likely
to get more high current strokes.

I got to try a Windom antenna over a really good ground system and was
pretty much amazed at the performance. The antenna was a
decommissioned LOM antenna waiting for the bulldozers for about 2
years. Good grounds certainly make a difference.

But, is there a difference in strike rate between grounded and
ungrounded towers of the same height. I would think that the difference
would be very small, and smaller as the height gets bigger.

Since the vast majority of commercial masts,towers,buildings used to
collect the stats are probably grounded (Because the code requires
it...), it might be hard to find decent data for "ungrounded" things.
(for one thing, the equipment used to collect the strike data, until
recently, probably measured the current spike on the grounding wire..
these days, you could use the RF lightning detection systems, and match
up strike locations against structure locations)

Maybe wooden poles? (which are only "sort of grounded")

'sort of grounded' is as good as grounded. The current that builds up
the charge to initiate the upward streamer is relatively small, that
can be seen in the use of the high value resistors commonly used to
'bleed off' charge from antennas. instead of bleeding it off they are
actually just equalizing it with the local ground potential, the same
as happens on a 'properly' grounded tower/vertical. in most cases you
won't find an amateur tower that isn't grounded one way or another
anyway, even if a specific ground rod or other system isn't supplied
at the base there is still a decent ground through the foundation.
and if not then there is through any cable going up the tower that
connects to a rotor or most antennas. it takes real work to really
insulate a tower from ground in such a way that it would not allow
charge attracted to the area under a downward leader from moving up
the tower... the large rf isolators and tower lighting isolators used
on base insulated AM broadcast towers are a good example... and even
on those types of towers you will hear reports of 'lots of snapping
and popping' before a stroke, those sounds are small flashovers of the

guy wire insulators as the charge flows up them toward the tower. So to do it right would mean using insulating guys also. Then, even if you got that far a tower of any height would end up going into corona at the bottom and top anyway due to the high vertical electric fields under a storm cloud... even if the corona didn't reach nearby ground conductors it would still collect/dissipate charge on the conducting vertical section which may still initiate a streamer. So the short answer is that i have not seen any comparison between grounded and ungrounded vertical structures.

That's what I'm thinking. I know my well grounded mast is not a
lightning magnet. Some years I get no strikes to it. In fact, I think
it's been a few since the last one. Well, unless it was hit when I
was not at home.
I'm still of the opinion that the ability of an object to stream means
more than if it's grounded or not.
Airplanes are not grounded, and they get popped all the time.
Trees are poorly grounded, and they get popped all the time.
I've known quite a few people over the years that stuck a vertical
on their roof and didn't ground it, and they got popped. Blew
the ungrounded antenna to smithereens too..
Many golfers get popped on the golf course and they are not
really grounded too well unless they are wearing spikes on their
shoes. :/
I think the height of the object relative to it's surroundings, and
it's ability to stream mean more than anything.
Trees are a target lightning pick probably as much as anything,
and most are fairly poorly grounded due to being wood with some
moisture to helps things a bit. I think the trees ability to stream
well is why they get picked on so often. The pointy ends of a
leaf stream well, much like the pointy hairs on the head of a
golfer. And when you have hundreds of leaves on a tree... :(

But lets say a grounded mast does get struck slightly more than
an ungrounded mast. That would not a logical reason to avoid
grounding it, when the act of grounding the mast pretty much
negates the likelihood of a strike doing much damage to the mast
or the building next to, or under it.

A wooden mast would act much the same as a tree if it did not
have any kind of ground wire running along it's length.
That's why I never use wood masts here.
I'd rather have a grounded mast struck every 5 years with no damage,
vs an ungrounded mast struck every 10 years that led to heavy
damage or even burned the house down.
So worrying about that is kind of silly I think, when you know
an ungrounded mast is big trouble if it ever does get hit.

2734. LOM Antenna

At my last QTH, lightning passed up my 40' grounded
tower, my 40' vertical antenna, and all the surrounding
power poles. It instead struck a nearby 6' tall live oak
tree that, on a sunny day, was in the shadow of the tower,
antenna, and power poles. Half of the tree died but the
other half survives.

Hi Mark,

There's another angle to be observed here. Globally, there is a potential difference between earth and sky that runs to several hundred volts per meter, with a current flow on the order of femtoAmperes per square cM. Not much locally, but for the full surface area of earth it is the electron conveyor belt charging the clouds through dust migration.

At this potential and current, absolutely everything is a short circuit that penetrates the voltage isoclines raising earth towards the clouds.

"The only problem with that is that the charge is so quickly
replenished
that I think trying to bleed off the charge is a waste of time."

The turn of the century genius, Testla, patented some lighting protection
devices based on having an insulated "cap" at the highest object on the
protected property. The "cap" would rise thousands of volts above the
protected structure and this would reduce the tendency of lightning to
strike.

Seems to me that the federal government has lots and lots of buildings and
would relatively inexpensively conduct definitive experiments to see what
works and what doesn't in the area of lightning protection.

So far as I know, the feds have done no such thing.

yes, they have, not that i believe everything the government has said,
but this stuff i do.

this presentation lists several reports by the navy and faa among
other agencies: http://www.docstoc.com/docs/4177489/Validity-of-the-Lightning-Elimination-Claim-Abdul-M-Mousa

the nfpa and others are quoted here, even though the author is
skeptical: http://www.straightdope.com/columns/read/2776/lightning-strikes-again

this one again quotes the onr, nasa, and air force studies as well as
others. http://lightning-protection-institute.com/fact-fallacy.htm

as far as tesla's stuff, i file it with most of the other experiments with lightning protection and prevention, if it really worked it would be used all over the place. the only system that has stood the test of time is the old franklin rod system, it doesn't prevent strikes, but it does try to provide a safe route to ground besides through the protected structure. much of the success of it depends on the quality of the installer, mostly how well they bond the various wires and how well they take it to ground.

This is done in some HV test laboratories to avoid flashover to the ceiling and to make the field more representative of "outdoors".. they hang a semiconductive curtain in a horizontal plane above the apparatus which charges up and makes what's above look less like "ground"

There's also the whole thing of surrounding a valuable structure (e.g. ammunition storage bunker, rocket launch pad) with an array of high towers with grounded wires from the tops of the towers. While no guarantee that lightning won't strike elsewhere, it definitely ups the odds of the protective structure taking the hit.

Read this if need more money.
I am engineer. I have been searching for a real money paying website about 1-1/2 years. Finally I found five which works just like an ATM. I have signed up and doing evaluvation of website work (real work is: wait for 30 seconds and then click the similar number shown at the top of webpage) and I have seen that money in my account was automatically increased. I exclaimed and became happy. After two weeks, I got a lot of money in my account. Yes it’s really working. Initially I didn’t believe it. But now I am earning money in dollars greater than my monthly income and using this extra income, I pay my internet bill, cellphone recharge, electric board bill, petrol bill, house rent and more. If you like to earn money just like me, open the URLs below in seperate windows and follow the procedure below.
Procedue: Open the links mentioned below in seperate windows and create an account by clicking register button in each page. After that earn money by clicking view ads button. View ads for 30 seconds and click the number mentioned. For example, Click number 5 if they mention Click 5. That all. Now money in your account is increasing in dollars.

Aviation, one of the first grunt jobs I had after working with the FAA was the decommissioning of an LOM site. The took out the equipment and the building but the antenna was there for several years. I didnt have a place I could put up a decent antenna so I would grab my 100 watt Icom and MFJ tuner and ride out to the site. I do mostly radar work now.

yeah, the nasa pads have towers and long sloped wires to try to catch
lightning also.

for hv work we mostly do it outside or in a very tall building (the octagonal one just left of center in the top picture is open inside and about 80' tall.

Dear Group:

Still not as clear as it could be. "Jimmie" is not talking about the 75 MHz yagi pointing straight up that provides a reference cone. The context seems to indicate a non-directional beacon that operated in the 200 kHz region using AM and a T antenna often supported by wooden poles. See: http://en.wikipedia.org/wiki/Locator_Outer_Marker

I recall, in an earlier life, 160 meters on a daytime-only AM broadcast antenna at night.

Yes an NDB, sorry I was a newbie back then with a hand that fit a shovel. I went into radar and automation instead of Navaids. Sorry for confusion. I think the site was called LOM/NDB. Sometime I confuse the heck out of all those acronyms. I never learned what most of them mean, just what they are. Stuff I work on like FDIO,SCIP,SRAP, I know what they are but cant tell you what the acronyms mean. Nav-aids stuff has really gotten foriegn to me over the years.

NDB is non directional beacon I forget what LOM stands for. It may have something to do with "outer marker". I believe that was part of the equipment and it was on centerline.

Yeah, the device in the pictue is usually just called a OM, MM, IM dependening on its position and has evolved from a wire antenna from when I got into the FAA to the double Yagi to the single Yagi . I havent been out there in a long time but I think there is a single yagi OM there now and all the wooded area is now turned in to condos.

Hi all,
I saw a site where a fellow designed a unit to measure impedance at 2.4 ghz, for use on wifi antennas. I don't recall if it was return loss or impedance.
It gave detailed instructions on how to build and he also had ready built units
for sale.
I think it was a ham that designed the unit. I also think he was not in the states, possibly a P or PY call sign, but the memory is not good!
Any help would be appreciated.
Thanks, Mike

A piece of Sage Wireline and a PCB to terminate it would be easier.

This is a copy of my reply to your duplicate posting to
alt.internet.wireless. Please don't do that again:

This one?
<http://pe2er.nl/wifiswr/index.htm>
or one of these:
<http://www.qsl.net/n9zia/wireless/appendixF.html>

What I do is use a return loss bridge as in:
<http://www.qsl.net/n9zia/wireless/pics/rtrn_loss_bridge.png>
I've built several out of chip resistors and junk parts. I have one
that works well up to about 8GHz. Great for testing antennas. That's
what's inside a Telonic Rho-tector (which can usually be found on eBay
for cheap). A few models go up to 2.4Ghz.

You'll also *might* need a microwave load or three. 50 ohms for a
reference, but also some other known values for calibration.

The problem is that you'll need an RF sweep generator to use this
effectively. It's also not a VNA (vector network analyzer) so it
won't tell you if any reactance is capacitive or inductive.

Clever but I think the OP wanted test equipment, not tuning methods.
Also, I noticed that the markers were set to 2400.500 and 2900.500MHz
instead of US band limits of 2400.0 and 2483.5Mhz.

So did the (plexiglas?) change the velocity factor for tuning.
Ya, I'll take his test equipment.

The plastic raised the dielectric constant of the space between the patch and the ground plane. In effect, it increased the effective wavelength of the patch slightly, thus lowering its tuned frequency. You can (accidentally) get the same effect by tuning the antenna, and then placing it inside a PVC radome, which will also slower its tuning frequency. The author will probably find himself re-tuning the plastic piece after he's installed the patch antenna in an enclosure.

>Ya, I'll take his test equipment.
> Mike

Build your own test equipment first. When that fails, mortgage the house, wife, kids, car, dog, cat, toys, etc and buy something better. However, beware of test equipment envy. Once you get on the test equipment upgrade path, nothing you own will be good enough, and there always will be something better.

Ahh, you are in the great RF black hole, according to some.

Anyhow, propagation to some of the places you haven't reached might be
problematic. Not really antenna problems.

Maybe time to download EZnec?

The OCF antenna can work very well. I put one up once because the place
where the coax dropped was really handy to my shack entrance. It worked
"well". I did some QRP into California on 80 meters during a contest,
and I worked what I heard. That doesn't specifically mean that the
antenna performed well, but it does mean that I worked QRP into
California on 80 from the middle of PA.

How will you model the radiating feedline? I suppose one could just put a "wire" in the model to represent the coax shield (which is what radiates) and tie it to something useful. Someone's probably figured out what the equivalent impedances are for the "isolator" and "balun" that form part of that antenna. Maybe googling "NEC model Carolina Windom" might turn up something useful.

That's pretty much what I would do re the wire. I suspect that the
pattern would be complex in any event. Richard was closest to correct
when he advised to listen to the manufacturer.

At first blush, I would think that the antenna is probably not far from
omnidirectional, but the horizontal component might skew it a bit. Any
rate, I don't think that his issues with working EU are antenna related.

Nice one of a kind solid brass straight key, on oak base. Real nice looking and feels great. My carpel tunnel is saying no to CW at this time..

This key was made by a ham in 4 land.

Pictures by e-mail Accepting best reasonable offer..

Radio Shack Pro 76 hand held 200 channel scanner.. Runs on 4 AA cells.

Also best reasonable offer.. Pic by e-mail..

I am looking for a Hy-Gain AV-18VS antenna.

> W9ZD

Rick,

On 80m it's almost omni-directional; worst-case eccentricity is around
4.5dB at 26 degrees elevation angle. The preferred directions are
broadside.

On 40m the pattern is more complex. At medium elevation angles (40-70
degrees) end-to-end is slightly better than broadside; at lower
elevation angles the pattern develops into 4 lobes NE/NW/SE/SW
(ssuming the antenna runs N-S)

Hope that helps,

Steve G3TXQ

2764. radials vs radialless @ 144/430 MHz - "stealth" antennae

Because of an antenna unfriendly neighborhood and limited space I am
considering using a Diamond antenna either with or without radials,
specifically X-50 vs SE-100.
They are the same length, but the SE-100 is a "marine" antenna without
radials. Nominally they both sport the same gain etc.

What are the tradeoffs?
Without radials it would certainly look less conspicious.

TIA

Marc

>Without radials it would certainly look less conspicious.

In an antenna of this sort, I believe that the primary function
of the radials is to act as a sort of feedline choke... they minimize
any tendency of RF coming up the inside of the feedline shield to flow
back down along the outside of the feedline. Such RF on the feedline
can cause radiation which will disturb the pattern of the antenna to
some extent.

A radial-less version of the antenna has no such choking, and there
might be some RF flow on the feedline as a result. This might cause a
slight reduction in gain in some directions, due to changes in the
antenna pattern.

If there's a *lot* of RF current flow on the outside of the feedline,
it might tend to couple into nearby conductors, and might (in some
installations) be the cause of QRM (e.g. TVI).

Is this likely to present a problem? In most installations I'd tend
to doubt it. If it is, you might be able to correct it by (1)
insulating the antenna from its mast, and (2) adding some sort of
choke to the feedline, just below the antenna feedpoint... either wind
a foot or two of the coax into a coil, or clamp a ferrite or two
around the coax.

Do what you wish but the ground radials on the diamond A50 are there
for a reason. It would be in your best interest to leave them on. It's
small enough to begin with that you should not have any problem hiding
it. I have one up and it's well hid at 30'.

Hi Dave,

I've modeled the conventional 4 radial GP, in free space; and, if
anything, the down lead (added as a 1/4 wave drop wire) supports more
current than the "radiator."

When I did the same thing with a ground plane of 120 radials (and the
added drop wire), the down lead supported nearly as much current as
the "radiator."

Neither radial configuration exhibits any/much choking.

In essence, these models were simply vertical dipoles with a star of
neutral elements. Of course, changing the length of the drop wire
complexifies the outcome; and would, I suspect, merely mimic nature.

Going further by following up on that last thought:

When for both radial configurations I vary the length of the down lead
(starting at 0.1 then adding 0.05 wl increments), the down lead shows
the current distribution of any inverted radiator that correlates to
that length (up to and including 3/4ths). However, the drive point
Z's R varies considerably ONLY around resonances (quarter and three
quarter wl) while the Z's X barely shifts value except (and again) at
those resonances.

What the elevated radials appear to do is dominate (buffer) the feed
point Z against variations of a feedline's length. Without these
radials, then this would be nothing other than a vertical Off Center
Dipole - if the feedline doesn't find ground, that is. The presence
of ground takes all bets off the table, but I don't think ground will
introduce choking action to the list of qualities for elevated
radials.

The Earth has the excess of electrons. The Earth produce the electric field
about one hundred volts per meter. In a suuny day the electrons migrate up
with the heavy ions (aggregates of H2O molecukes).

> with a current flow on the order of
> femtoAmperes per square cM. Not much locally, but for the full

This "electron conveyor belt" charge the air. Next the air becomes cooler
and the condensation take place. Clouds appear. The condensation cause the
voltage rise. All types of sparks jump.
Under clouds the electric field has the opposite direction and thousands
volts per meter.

>
> At this potential and current, absolutely everything is a short
> circuit that penetrates the voltage isoclines raising earth towards
> the clouds.

The high voltagi in the clouds is lowered by the "electron conveyor belt"
and the lightning.

The "electron conveyor belt" is more effective if the Earth have many sharp
needle.
So there are the two possibilities:

1. If "The intention is to PREVENT a direct lightning strike," - many sharp
needle is used,

2. If the intention is to CATCH a direct lightning strike and conduct a
strike to ground - a polished big ball is used.

In the early days of lightning conductors, I believe that the French
didn't like the nasty pointy things which the British had installed.
Instead, they decorated theirs with fancy balls at the top - with
sometimes disastrous results.

Source record: 12383
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I'm trying to model an FM transmitter with LTspice. The schematic of the circuit I'm trying to model is shown here:

http://www.sentex.ca/~mec1995/circ/fmt1.htm

It takes a while to start oscillating, but when it does reach a steady oscillation, the lower half of the waveforms look a little distorted. Interestingly, when I reduce the inductor value (to say .01uH), the waveforms are less distorted, but when I only decrease the capacitor (to say 3pF), the waveforms become more distorted. Any insight into the source of this distortion?

Could it be that I need to model an equivalent antenna?

I've copied the LTspice .asc file below.

Thanks in advance!
Dave

What are you trying to find out with your simulation? Simulation is usually either pointless or time consuming unless you have some narrow thing to look for, and have a good idea what it is.

I suspect that the waveform distortion is related to the impedance of the tank more than the resonant frequency. Reducing the inductor value lowers impedance and raises frequency; reducing the capacitor value raises impedance and frequency together.

Yes, you probably need to model an equivalent antenna. In fact, for many things you may want to find out from simulation you would need to model several different equivalent antennas.

In order to start, an oscillator has a loop gain greater than one. This causes the oscillation amplitude to continually increase. Eventually, the amplitude is limited by something nonlinear, since it can't increase forever. Oscillators designed for low noise, high stability, or other precise characteristics have some stable limiting mechanism such as diodes to limit the amplitude at a known value. Most, like this one, depend on distortion caused by overdriving one or both transistors to limit the amplitude. Consequently, distortion virtually always occurs(*). To get a clean output requires filtering, and the more distortion in the basic feedback waveform, the better the filtering required. All this circuit has is a single tank circuit in one transistor collector. The loaded Q of this circuit is just too low and the fundamental distortion too great to get a clean waveform. Adding an antenna might help or hurt the distortion, depending on the type of antenna -- it might filter some harmonics but not others, and at resonance it'll further load the tank. You might try tapping the collector and antenna down on the tank, but I'd be prone to add some additional filtering between the tank and antenna. Even that might not work as you expect because of the complex way the antenna impedance changes with frequency, but it'll help.

(*) It's usually not practical to filter audio oscillators, so some low distortion audio oscillators are made by using feedback limiting that has a very slow time constant -- one that's many cycles of the waveform.

A light bulb is often used for the limiter. In general, you can trade loop gain for distortion -- the closer you make the loop gain in the linear region to 1, the less distortion you get. But the slower it starts, and it won't start at all if anything like temperature or component value variation drops the loop gain below 1.

Whoever said to expect something like a clean signal from a
transmitter like that in the first place. I ve build a few of those
little toy FM transmitters and the output is far from clean. Unless
this is just an exercise in Spice modeling
its probably a waste of time to do so. Intead of worrying about the

antenna I would try to figure out what was the best load for the circuit and design an antenna to meet that requirement otherwise I would just hang a 8 inch piece of hookup wire off it aand call it done.

I use the Arrow 2m/70cm Jpole which works well. No radials, of course, and small in size which could be used in the attic. They're made of solid aluminum stock and are as bulletproof as an antenna can be made. Check arrow's website, I think you'll be impressed

I've got one and it works well. It resembles an
end-fed Zepp more than a J-Pole.

I ran the file. It looks like the output voltage is forward biasing the
collector-base junction of the output transistor Q2 , causing some
clipping. Q2 is saturating.

I was going to suggest that if he wants a clean signal he should probably
filter the snot out of the signal, and maybe even buffer it.

But he didn't ask...

That would be my guess too....I suspect you have set the output tuned
circuit Q way high. Tapping the antenna into the coil might serve you
better, and placing a small resistor in the emitter path before the
feedback cap would hold the gain down, but planting a resistor to
represent the antenna load might do the trick right there??

2782. Re: Antenna Pattern: Carolina Windom

Newsgroup: rec.radio.amateur.antenna
Date: 2009-10-22 01:21:49 UTC
From: David Thompson <thompson@mindspring.com>
Message-ID: <5PadnTN_ttswLkLXnZ2dnUVZ_o-dnZ2d@earthlink.com>
Source record: 12394

I have a Carolina Short 80 formerly called the Carolina 80 Beam up. Its been up since about 1990 and is a good performer.

On 80 it does good off the ends but has a skewed figure 8. My antenna is broadside N and S. K4UEE told me that from the Juan Fernandez operation a few years back I was about the loudest on 75 SSB. I regularly worked EM1 from near the South pole with 9+ both ways. On 20 the pattern is still a figure 8 but with a big lobe off the ends so I worked VK and ZL from Georgia one year in the Oceania Contest.

I have two vertical short dipoles on 75 and 80 and another Carolina Short 80 broadside say NE/SW would probably do as good. To be really effective you have to get it up at lesat 50 feet and higher is better!

My version of the Short 80 is only 84 feet horizontal.
I have the three vertical sections with the one at the feedpoint radiating. The DMU matching 52 ohm coax to the 300 ohm point. The DMU also lets the shield radiate. The 22 foot piece of coax teminates in a Line Isolator balun to cut the radiation to the shack at that point.

Just wish Radio Works would fully explain the antenna. It is very difficult to model but thanks to Dr. Dave then W0MHS (now W7FB) he ran it on his mainframe modeling program. We never got NEC to show us anything beyond a OCF windom model.

The above apply to grounded tower.

For:
" But, is there a difference in strike rate between grounded and
> ungrounded towers of the same height. I would think that the difference
> would be very small, and smaller as the height gets bigger."

You wrote: "I'd rather have a grounded mast struck every 5 years with no
damage,
vs an ungrounded mast struck every 10 years that led to heavy
damage or even burned the house down.
So worrying about that is kind of silly I think, when you know
an ungrounded mast is big trouble if it ever does get hit."

The grounded tower catch the electrons in form of "electron conveyer belt"
and lightning. If the "belt" is efective enough no lightnings. All local
exces of electrons from the cloud flow without lightning. If no the
lightning appears but it is weak (the sum of electrons is the same).

The strike in the ungrouded tower is always strong.
So You are right.

no, that is not right. a grounded tower can not dissipate enough
charge to reduce the stroke intensity. towers actually attract MORE
high current strokes than the surrounding ground.

Well, Szechuan obviously hasn't figured out which way the belt is
pumping electrons, so it's not surprising he's wrong. He also doesn't
understand anything of the physics involved, either, so none of his
nonsensical answers should be a surprise.

Grounded towers with the many spikes dissipate more charge then the simmilar towers with the polished big ball.
That with the many spikes PREVENT (or minimalise), that with the balls CATCH (high current strokes).

The atmospheric electricity was described in XIX century. At that time
Armstrong and Kelvin build the High Voltage Generators (steam and drop).
Also the way how the spikes work.
Have you the old books?

Much of this is speculation.

With 10 million volts; currents of 10,000 amperes and strokes that can
travel 30 miles: whether you have a ball or a spike on top of a roof
isn't going to make much difference.

It has been shown that a properly installed lightning rod system; and UL
rated materials connected to low resistance grounds will increase the
odds of protecting lives and property substantially.

(The TV stations on top the Sears tower in Chicago continue to transmit
even as they are being struck.)

I find that the new books have the good information that has been well proved over the last 100 years or so. There were lots of theories in those old books that have been proved false over the years. It also helps to work in the field, at the hv lab i work at we can run 3 phase 765kv, +/- 1Mv dc, and about 5Mv pulses. one of my personal jobs is writing software for lightning protection design on hv power lines, so i have been through this stuff many times.

The volts appear when no chance to dissipation. To have it on the roof must
be multiplicity of spikes (not one).

I assume a certain biased reporting of anecdotal evidence.:-)

A ball at the top hat of a Tesla coil allows a greater
amplitude of voltage to build up before arcing than does
a point at the top. Therefore:

Points should result in more lightning strikes at lower
voltages.

Balls should result in fewer lightning strikes at lower
voltages.

Can't think of any valid reason why either design
should be able to avoid the really big one.

Did you mean 'higher'?

>Can't think of any valid reason why either design
>should be able to avoid the really big one.

Surely, when lightning is about, points allow an essentially continuous
discharge at a low current, while balls allow the voltage to build up
and up, until there is a big 'splat'?

Two people separated by a common language? :-)

Allow me to rephrase: When the voltages are low,
the ball will tend to discourage the lightning
strikes because the voltage may be too low to
achieve the ionizing threshold potential
surrounding the ball.

In the end, that's about the way I see it, but I consider
any discharge by either to really be fairly irrelevant.
Trying to avoid strikes by discharge is like whizzing in
a whirlwind. :/
The sharp point streams much easier than the ball,
so the chances of streaming and connected to a down
leader are much greater than with a ball which will
resists streaming at those same potentials.
If you had a spike next to a ball, I would think the spike

would be struck most of the time. You need a good
streamer going to lure a down leader.
But a ball can still stream if the potential cranks up
high enough, and the resulting strike can often be a
a stout one if it can overcome the poor streaming
of the smooth ball.
Both masts should be well grounded.
It's not an accident that most lightning rods have
a sharp point, the same way as most flag poles
have a round ball on top.
One is designed to stream as well as possible in
order to become a more likely target than what it
protects, and the other is designed to stream poorly
to resist strikes compared to the other better streaming
objects near it.
No streamer, no cloud to ground lightning at that
point on the earth. BTW, I've got pictures of streamers.
You can see them at night, and they bend and point to
the down leader as it approaches the earth.
The first one it can connect to forms the final path to
ground, and I think this is in the last 150 yards or so
if I remember right. The leader traveling in appx 150
yard or so steps through the sky.

Trying to avoid strikes by discharge is like whizzing in
a whirlwind. :/
The sharp point streams much easier than the ball,
so the chances of streaming and connected to a down
leader

No down lider. Excess of electrons is in the stormcloud and they jumps if the difference of voltage exists. At first they jump inside cloud. Next they jump in the all directions outside cloud. But the all jumps are in form of oscillations. Lightnings produce LW.

>are much greater than with a ball which will
resists streaming at those same potentials.
If you had a spike next to a ball, I would think the spike
would be struck most of the time.

We need here the experimental data. Does anybody know?

> You need a good streamer going to lure a down leader.
But a ball can still stream if the potential cranks up
high enough, and the resulting strike can often be a
a stout one if it can overcome the poor streaming
of the smooth ball.

The only cause for spark jump is the voltage difference. Spikes decrease it.

>Both masts should be well grounded.
It's not an accident that most lightning rods have
a sharp point, the same way as most flag poles
have a round ball on top.

Is the ball grounded?

>One is designed to stream as well as possible in
order to become a more likely target than what it
protects, and the other is designed to stream poorly
to resist strikes compared to the other better streaming
objects near it.

Lightning (electrons) strike the Earth. Grounded ball has the voltage like the Earth. Nongrounded like the air. Such are neutral. Does not prevent and not catch. But may be attacked like all.

>No streamer, no cloud to ground lightning at that>
point on the earth. BTW, I've got pictures of streamers.
You can see them at night, and they bend and point to
the down leader as it approaches the earth.
The first one it can connect to forms the final path to
ground, and I think this is in the last 150 yards or so
if I remember right. The leader traveling in appx 150
yard or so steps through the sky.

The oscilations start from very short in all directions and the last steps are longest.

no they don't. they provide a better place for streamers to start
because the sharp point increases the voltage gradient helping it to
stream sooner.

> >

there are no oscillation in the step process. and there is no
evidence that the steps change length in any report i have seen.

But the upwards liders are also possible. If downward lider oscillate close
the high metal tower the electrons in the metal also oscillate and can jump
out. But that are details.

But it is obvious. Each spark is in form of oscillations. No matter if the
"electrods" are steady or the distance is increasing.
It was discovered by observing the tissue punched by the spark (XIX
century).
In nowadays reports no obvious thinks.

it may be obvious to you, but that doesn't make it true. a spark is
not a form of oscillation. and leaders are not sparks. sparks are a
very specific phenomenon that is a very short lived breakdown over a
short distance. leaders and streamers are long term conductive
channels caused by a channel of charge accumulated in them and are
progressive breakdowns over long distances. The physics are very
different, but in neither are there oscillations. again you go back
to ancient history, it is time you updated your reading list.

This is with the full agreement with me (in fundamentals).
It is not easy to read, with the understanding, the electric schemes
(diagrams).

Look at the page 3. The arrows represent the currents. So the electrons flow
in opposite direction. So in sunny day they migrate up. Very up (18 km at
equator).
The next symbols are the "+" and "-". What they means on this scheme.
Electrons migrate very up, but always on the droplets of water (heavy ions),
so in the air is the excess of electrons if there are the heavy ions. But
what the voltage is there?
You remember: small drops - smal voltage (Kelvin's drops generator). Next
cooling and condensation take place and larger droplets fall down. But on
the larger drops the voltage is higher.
The "+" and "-" on electric schemes are use to indicate the direction of the
current flow. Electrons flow from "-" to "+". No matter how many electrons
is.
But that everywhere in the atmosphere is excess of electrons should be
obvious for you now. You know that on the surface of the Earth is also
always the excess of electrons. But the current flow " if the difference of
voltage exists".

Not elecricians think that "-" indicate the excess of electrons and "+" the
deficit. Such is in physics.
The scheme on the page 3 was drawn by electricians.
Do you agree? (Richard asks: get it?)

All breakdown are made by oscillating electrons. They work like the
pneumatic hammer. When electron oscillate (like in the Kundt's tube) at the
end the voltage is doubled and the next distance is progressed.

">>> Lightnings produce LW.
>
> >yes, there are downward leaders. these can be tracked either by their

In ECM such initial oscillations are detected and the power is shut down
before full breakdown.

The electrons have mass and charge - they like oscyllate. They oscillate before the full breakdown and after to dissipate the full energy. In the channel are better conditions to oscillations than in the conductor.

you make assertions that are simply not true. i am sorry, but there
is no use continuing this discussion as you do not understand the
basic physics and insist on quoting outdated and incorrect theories.
when you have taken some modern physics courses and are up to speed on
the state of the art today, or even yesterday, but at least better
than last century maybe we can continue, but this is a waste of time
for all now.

Depends on the type of roof and frequency you're working. If the roof
absorbs (small amounts of) water, or if water can stand on the roof,
then I'd say: Yes. Wet trees can also absorb radio waves better then dry
ones. Don't see why roofs are any different.
HF will suffer most, VHF and UHF will probably not be affected as much.
But I've spoken to a local 2m amateur with indoor antenna who claimed to
notice the difference between wet and dry.

You must live where it never freezes. The difference between summer and winter on 2m and up is certainly noticeable and measurable here in Minnesota.

Oops, forgot to say that water, even with the contaminants of life in
it, doesn't conduct very well when frozen.

The original question had to do with interference with radio
reception, not with conduction.

I was responding to "wet" versus "dead".

What planet do you live on?

Interference had nothing to do with the discussion.

Conduction of objects in the local environment has everything to do with
reception.

Your license is new in August this year. And tied to a canceled
callsign in 1999. Odd history.

Just to be clear, I was first licensed in 1991, never "cancelled",
upgraded in August 2009.

And why does Tom choose to spread disinformation as part of this
discussion?

It's always interesting in a car-wreck kind of way when someone can't
come up with something better to say so they take out their credibility
and blow it to smithereens.

2834. FS: NEW Minicircuits ZKL-1R5 RF MICROWAVE AMPLIFIER(s) 10MHz-1.5GHz. $38.70 or $50 on Ebay [LOT of TEN, ZKL1R5]

Newsgroup: rec.radio.amateur.antenna
Date: 2009-10-28 20:48:59 UTC
From: Mark Licetti <StanStar@nyc.rr.com>
Message-ID: <0c9b2d26-cc45-44ab-899d-4c1ed885be22@x6g2000prc.googlegroups.com>
Source record: 12296
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

LOT of TEN or Singles.
Minicircuits ZKL-1R5 [ZKL1R5] RF MICROWAVE AMPLIFIER(s), Wideband 10MHz-1.5GHz.
High-end Amps, MedPower +18.7dBm, LowNoise 3dB, Gain 39-40dB. NEW - in original Minicircuits/antistatic packaging (never used, USA origin & location, ships worldwide).
Either Singles or entire LOT (price shown for a Lot, but message us if you want single(s) - shipping is CHEAPER than shown ($5.20), etc. however on a quantity basis you save by dealing as a Lot, not Singles - message us if you just need a few, not all 10 units).

Posted on Ebay, item# 330371507322 - goto www.ebay.com & enter 330371507322 into search. "BuyNow" OPTION is AVAILABLE - NO need to wait for Auction ending.
Contact via Ebay (best) or Email. By Email, can hit "Reply" in Newsgroups but REMOVE "nospam" strings if appears in my address (edit address manually, but sometimes it’s already done) so I could respond from a real address/name. Do NOT reply on Newsgroups (I posted here, but will NOT read), and if I get much spam that address will be DISABLED, so you'll have to communicate via Ebay (which, incidentally, is more secure anyway). My Ebay feedback is 100% positive, not to mention 14 YEARS of Newsgroups trading without complains. Again, description is on Ebay but a few facts are copied here (for convenience):

** TECHNICAL SPECS:
A DATASHEET PDF is at manufacturer's site www.minicircuits.com-->enter "ZKL-1R5" into search--> datasheet (do not omit dash, ZKL1R5 instead of ZKL-1R5 will result in an error); so only a few specs are copied below. Finally, check the price Minicircuits is asking - $150/unit, we're asking $39 "auction start" & $56 "buynow" options - new/sealed units but @33% cost (reason to sell is explained below)
** PHOTOS are at EXTERNAL SERVER (as I CANNOT POST on EBAY for free beyond 1st free photo); at http://photos.starium.org ----> select Gallery named "Minicircuits ZKL-1R5"..
• Wideband, 10MHz to 1.500 GHz
• IP3 +31 dBm typ.
• LowNoise 3 dB typ. (not bad for a MedPower amp, rather than dedicated LNA)
• Gain 40 dB typ., Flatness 1.2dB
• VSWR IN 1.4, OUT 1.6
• P1dB Compression Point +15dB min, however charts indicate 17.6 to 18.7dBm

• Connectors - SMA (50 Ohm impedance), gold-plated.
• DCpower +12V nom @115mA max, but will take a range of 9-13V or wider.
• More data, plots, etc. are in a datasheet (PDF) downloadable from manufacturer's website.
Example of applications: communication systems e.g. cellular, satellite distribution, GSM/ISM; Radars, we're using them in a Middle-Stage Amplifier block in an MRI (magnetic) scientific instrument.

** REASON to SELL::
Our RF Engineer has changed Product design in which this amplifier was previously used (a scientific instrument); so not all purchased lots of ZKL-1R5 could be finished before new design "kicked in". In the new design, ZKL1R5 overloads the newly designed next amplifying stage (which became more sensitive) & we don't know a clean way to attenuate ZKL1R5's gain (38-40dB!, lowering powersupply is not a solution & not enough). So instead we switched to using ZFL-500 amps with lower gain & narrower bandwidth (0.5Ghz, in fact all we need is 0.2GHz, not even 0.5GHz). Minicircuit's policy is not to take them back & it's laborious to try to retrofit these into a new system - it's better if we simply sell, at a loss or not, but it's easier. We're already stocked on 60 ZFL-500's, so design change is permanent/verified.

I, in fact, come from a competing RF company (not to be mentioned) so not interested in promoting Minicircuits, but this is one of Minicircuits better models; as far as I know it's using Gallium/Indium PHEMT/etc. FET’s or something to that effect, not surprising but $150 price is already difficult to attain, yet we ask even 3-4x times less or to exchange for ZFL500 (Minicircuits said ‘no”). It's a pity at the new company where I moved in 2008, which is using RF Amps (not designing them), we cannot use ZKL1R5 due to gain excessive for a new design (was normal in an older design), also we decided don't need 1.5GHz expensive amps considering our signals are under 200MHz.

P.S. Again, more photos are at that http://photos.starium.org site - pictures are better than a lengthy verbal description.

Hi Mike

Welcome. By "great conversations" you are sure to read unusual ones,
interesting ones, some that are downright odd, some that are venal,
political too (if that wasn't already covered under the other
categories).

And you might read something about antennas. There are any number of
topics that are sure-fire. Usually the more elemental that topic is,
the longer the discussion (like the loss in a transmission line under
various loads) will be.

In the main window, click Help, then Contents. This is the EZNEC manual. In the manual, locate the Test Drive chapter, which is a tutorial for using EZNEC. The Test Drive section A Lap Around Track 5 covers L networks and other features new to v. 5.0. For additional information about L networks, open the L Network Window by clicking the L Networks line in the main program window, then press the F1 (context sensitive help) key.

```
Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Try a Google on something like 'sinewave voltage current waveform' etc.
It's surprisingly difficult to get good examples of waveforms, but some
are here:
http://www.allaboutcircuits.com/vol_2/chpt_1/2.html
http://www.pcguide.com/ref/power/ext/ups/funcOutput-c.html
http://www.tpub.com/neets/book2/1g.htm

Just Googling Sine wave gave lots of examples.

Google is clearly a closely guarded secret. Lots of people in groups
that I subscribe to have clearly never heard of it. The odd thing is
that it must take them longer to type their question than it would take
them to find the answer.

Google? Well, I searched Google and Bing! for nearly an hour, and found
dozens and dozens and dozens of sine waves. Unfortunately most of them
had superfluous embellishments and/or were of poor graphics quality,
making them totally unsuitable for my purposes.

I promise to try harder in future .....

Plonk!

I will take another run at it.
Understanding the program is the goal, I can solve the problem by
taking the output of EZNEC to TLW.

Thanks again for the EZNEC program!

OK it's overkill, but LTSpice will generate almost any waveform you want
and you can capture as a bitmap.

Somewhere out there on the internet, there's a site where you can build
(or, more accurately, 'synthesise') your own waveform from its
individual components. It's great fun and very instructive.
Unfortunately, I can't find it at the moment (but I'm looking).

Thanks.

But what a bloody awful website! It's more or less unreadable (at least in OE8). If I try Safari, all I get is a light blue screen, and a message saying that I need Abobe Player 10 (and I've already got V10.0.32.18) installed.

Nothing seems to do very much, but I'll have another look at it later on.

But no, It's definitely not the website I was thinking about. I'm sure I have a link to it. Will look later (after I've swept a load of leaves up!).

2867. Matching impedance with coax

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-04 01:45:39 UTC
From: amdx <amdx@knology.net>
Message-ID: <8fb2d$4af0dcbd$18ec6dd7$28165@KNOLOGY.NET>
Source record: 12329
Cross-posted to: alt.internet.wireless,rec.radio.amateur.antenna

Hi all,
I'm trying to get an understanding of the MFJ-1800 wifi antenna.
The antenna has a folded loop as the active element.
Is this considered to have a 300 ohm output impedance?
The folded loop is connected to 2.11 inches of 50 ohm coax
that goes to an N connector. The coax has 4 torroids on it.
It looks like a polyethylene core material. So I used .66 as a VF.
With that I get a .66 wavelength of at 2.437 Ghz for the 2.11" coax.
(yes same .66, that's just the way it worked out)
So I think I'm matching 300 ohms to 50 ohms, but I don't
see how .66 wavelength of 50 ohm coax does that.
Fill in the details please.
Here's a picture of the MFJ.
http://www.gigaparts.com/parts/gpcpa/original/nw0054.jpg

Thanks, Mike

>The antenna has a folded loop as the active element.
>Is this considered to have a 300 ohm output impedance?

Not necessarily.

A folded dipole will have a 300-ohm impedance only under certain conditions of design and use. The feedpoint impedance depends on several factors, including:

- The ratio of the diameters of the two elements (usually 1:1 in common folded dipoles, but not always the case), and

- The ratio between the element diameter(s), and the spacing between the two elements, and

- The surrounding environment

The commonest case (of which you're thinking) is a 1:1 ratio of element diameters, a relatively small spacing, and a free-space environment (i.e. no other conductors nearby). In this case, the folded dipole will have a feedpoint impedance of roughly 300 ohms.

However, in the case of the MFJ antenna, the third of these conditions is very different. The FD is not in free space - there's a reflector on one side of it, and a set of directors on the other.

The presence of these "parasitic" elements will greatly change the feedpoint impedance of the FD... typically, to a lower value. Close enough spacing of the parasitics can reduce the feedpoint impedance by quite a lot.

I suspect that the design of the MFJ antenna was done in a way which places the parasitic elements close enough to reduce the folded dipole's impedance to somewhere in the neighborhood of 50 ohms. All that would be necessary, then, to allow a direct feed from a 50-ohm coax, would be a choke balun (to convert the unbalanced coax feed to a balanced drive to the folded dipole, without altering the impedance).

The 4 toroids on the coax stub will serve as a tolerable (less than perfect, but probably usable) choke balun.

The FD's impedance probably isn't supremely close to 50 ohms... there could be some mismatch and thus an SWR of greater than 1:1. However,

the losses in the coax stub, and in the main coaxial feedline, are going to be high enough to reduce the *effective* SWR (as seen by the radio) to a lower value... close enough to 1:1 that the transmitter won't be unhappy.

To sum it up: the matching is being performed by the antenna design rather than by the coaxial stub or by any separate matching network.

You might want to search for info on the WA5VJB "Cheap Yagi" design. Kent Britain figure out a way to make a very simple, effective Yagi antenna (out of scrap parts, in effect) with a 50-ohm feedpoint impedance and no separate matching network or gamma match. It's done by the combination of a "half-folded dipole" driven element, and proper choice of the spacing for the reflector and first director.

Greetings:

Building a 4 square antenna system: How should I tune each
element? should I place a 50 ohm load on three elements then tune
up one using my MFJ 259 after that element is tuned place the 50 ohm
load on it then tune up the next element repeat till all have been
tuned?

OR should I short the other three elements to the counterpoise tune
the element them repeat till all have been tuned?

Or should the three be left floating then tune the one then
repeat till all have been tuned?

How much loss does 2-1/8 inches of rg-58 have at 2.4Ghz?
I calculate it as 0.036db, how does that contribute to cable matching?
Inquiring minds want to know.
Mike

The presense and spacing of the parasitic elements isn't going to
change the feedpoint impedance that much.

Mike needs to check out - and understand - how a side-mount folded
dipole is matched to a 50 ohm line. I'm sure this yagi will simply
use a similar series coax balun.

No, but I understand that some cellphones use "SMS" in morse to signal
an incoming text message (Short Message Service); maybe that's what
you're hearing.

I guess I've never seen that commercial, so I don't know if that makes
any sense in its context.

I recall that decades ago, there was an FCC prohibition against the inclusion of the SOS pro-signal in commercial radio and television broadcasts. You weren't supposed to ever transmit this signal unless you were actually in distress.

TV shows would either just *refer* to their being an SOS in progress, or would transit some other Morse code signal as a substitute, or both. I remember one Star Trek episode in which the substitute signal was actually a very-low-speed FSK signal (high and low tones, about an octave apart).

I don't know whether the legal prohibition against transmitting SOS on commercial radio/TV still exists today, or whether it was dropped during the big deregulation.

Wrong. It can change it a lot. It can take a 50 ohm DE and move it to
10 ohms or less. And then there's the reactive part.

I suppose this guy is trying to be funny when he talks about radials
choking the current flowing on the outside of the coax. that's the

job for Baluns.

Radials are installed on vertical antennas to supply return RF current flow back up to the other half (the vertical) of the antenna. Without radials, you only have half an antenna. The placement, length, and number of radials have a very definite effect not only on the resonant frequency, but also on the SWR attainable.

Yes, it was dropped a long time ago.

To answer another posting at the same time, the brand of cell phones is Nokia.
The default SMS alert is the morse code SMS.

BTW, it was never SOS as three seperate letters, the official distress call
---
was SOS (written with a line over it) the three letters run together such as
we do for SK.

It was in marine use preceded with a long dash (I'm not a marine operator
so I don't know how long) to trigger automated monitoring equipment,
but that was a relatively modern invention. (1950's??)

That way words like Sosnow (the name of my high school auto shop teacher)
would not cause a problem.

Geoff.

It sounds like you're wanting to adjust their impedances. Why? You realize, of course, that as soon as they're all excited, the element impedances will change dramatically. One element in a typical 4 square array will actually have a negative radiation resistance.

There's a lot of information about feeding phased arrays including 4 square arrays in Chapter 8 of the ARRL Antenna Book. It was completely re-written for the latest (21st) edition. ON4UN's _Low-Band DXing_ contains some good information also.

If you are using one of the commercial hybrid phasing networks or one
designed from the 4u1un book proceedure then the normal method is
this:
1. erect ONLY one vertical with its intended ground system.
2. feed it with 50 ohm line and adjust length for resonance at the
center frequency you want
3. replace 50 ohm line with 1/4 wave 75 ohm foam coax (must be foam or
1/4 wave won't reach corners of standard 1/4 wave spaced elements)
4. build other 3 elements identical to the first one.

Geoff,

A series of twelve four-second dashes, spaced one second apart, was sent by an automatic keyer on 500 kHz. Any automatic distress receiver in the vicinity would be triggered to operate an alarm after picking up four dashes. The extra dashes were to overcome atmospheric noise and increase the chance of the signals being picked up. Four consecutive dashes meant that the automatic alarm wasn't triggered too often in the tropics.

The Radio Officer would be woken in his cabin by a bell and had 2 minutes to get to the radio room and switch the main receiver on to receive the

distress message. Sometimes the alarm would go off half a dozen times in a night during storms around the European coast in winter. Didn't get a lot of sleep for several days sometimes.

Regards

Mike G0ULI

No relation to anyone you are thinking_of/describing/etc, sorry to
ruin your conspiracy theory.

If you want to try and achieve a match to 50 ohms by moving the
adjacent parasitic elements seriously close to the driven folded
dipole, go for it. (I could dust off trusty Elnec and get a result.)
But I'd be surprised if anyone who gives a rats about the consistency
of the result would go down that path.

I am very familair with how the commercial side-mounted dipoles and
yagis are manufactured here in Australia, and I doubt that the rest of
the world is dramatically different. In three simple words - series
coax transformer. Let's agree that with an SMD you don't have
parasitics to play around with - except for tower spacing (which has
an impact on pattern, and variations are used for that end.) The
Aussie manufacturers use eaxactly the same method on the FD on their
yagis. That is why I suggested the O/P look into that approach.

They looked for the spammers and assorted other trash forum and
couldn't find it. (grin)

Okay, let's fix this problem. First take a really deep breath or ten.
Then maybe a glass of your favorite adult beverage if you like. Just one
or two though. More than that can make the problem worse.

Now, this really isn't a forum, it's a newsgroup. There is just no way
you are king to stop the crazies from posting here. If you're adamant
about not seeing anything you don't like, and you want to fight them,
you'll lose.

Hope is here though. Your newsreader has a method of not seeing the
offensive posts. It's a filter. Also known as a killfile, bozo bin, etc.
Ease of use varies between newsreaders. But they do work pretty well.

So there ya go. You can calm down now and enjoy the non-crazy parts of
the newsgroups. This is a pretty good one - even our eccentrics are a
good read!

Your confirmation here doesn't ruin anything. Art would hug you no matter how you sign. Those he does have a remarkable need for retaining anonymity. He would have us believe it's because his supporters are easily bruised in the jostle. The following comment would support that:

>...gives a rats about the consistency
>of the result would go down that path.

which is another but perhaps left-handed confirmation.

This is RADIOBANTER.COM not politics.com or obama.com which is where everyone makes their first mistake! That TRASH doesn't BELONG here. This a site for RADIO oriented articles,so why are people so dense they can't figure this out until someone has to break out the crayons and draw them a picture?? Post that crap on cnn.com or some OTHER political website!
Wanna talk about RADIO then stay here,otherwise scroll to ANOTHER site!
This sh*t is getting old! I feel like I'm explaining this to a bunch of damn 3rd graders!!!!
Ok,rant mode off. F*CK IT!

Whatever - and whoever Art is. I wonder why people like you carry on
at a personal level towards posters whose views you don't share. And
you seem to need the limelight, posting a name and callsign.

I'm describing how the matching IS done commercially. You can crap on
forever if you wish about how you might do it. Fini.

Yeah, as a longstanding convention for thousands of posters here, it
is a strange thing about being public and open in this world isn't it?

If you can't put your name to it, then any posting is only vacant
spam. "No one at home" informs us all about quality.

On the other hand, you choosing to be anonymous means you could have
us believe you are writing from a cave on the Afghan/Pakistan border
while waiting for your dialysis treatment to finish. Only Ossama and
vampires avoid the limelight - as you call it.

>I'm describing how the matching IS done commercially.

Your painted-into-the-corner explanation has nothing to do with the
correlation between exhibited low feedpoint R and the proximity of
passive elements to what would have ordinarily been a very HiZ folded
element.

>Fini.

We shall await your next post as elevator@onefloorshortofthetop.org

The "ways it's done commercially" depends a lot on the desired result.

A choked line into a 50 ohm DE is an easy to do but not optimal method.

It doesn't give best gain or BW or best F/B or best noise temperature
and never ever gives the best combination of them for weak signal work.

But it IS easy.

And it's not always what the commercial antenna builders use. It's what
you have noticed that they sell. Or you might be pushing how much it's
used just a bit.

Then it's a point driven against ground that you need. Or a 2 point dipole. Either one with a lossless transmission line would work.

That's the only thing that will do all you want and do both RHC and LHC polarizations and do it at all frequencies. I have to assume you want all frequencies since you haven't responded on that question.

And it will have a very unusable impedance at all frequencies. But if you can do the lossless line, you are probably covered on the lossless tuner, too.

Good luck. You want everything, and you can't have it.

And "single circulation" is not the proper terminology (as usual), although I am somewhat sure about what you meant.

>change the feedpoint impedance that much.

Ummm... try again. If you simplify the antenna, the feed point
impedance of a 2 element yagi (just driven element and reflector) is
roughly the same as a dipole over a perfect ground. There are plenty
of graphs online to show how the impedance varies:
<http://extranosjacal.blogspot.com/2009/06/antenna-z-and-height-above-ground.html>
Note that the impedance of a simple dipole varies from nearly zero for
very close to the ground, to a max of about 100 ohms at about 0.35
wavelengths. A folded dipole will behave similarly, with a nominal
impedance of about 277 ohms, but varying over roughly zero to perhaps
450 ohms impedance. Add a director (or more director elements) and
available range of impedances changes even more.

>Mike needs to check out - and understand - how a side-mount folded
>dipole is matched to a 50 ohm line.

Assuming the folded dipole is the traditional 300 ohms, I usually
match it with a 1/2 wavelength 4:1 balun. At 2.4 GHz, it would look
something like:
<http://pe2er.nl/wifisector/>
Scroll down to the diagram and photo of the coax balun. I use
semi-rigid 0.141 coax, not RG-316.

>I'm sure this yagi will simply
>use a similar series coax balun.

I'm not so sure. The photos on the MFJ web pile seem to be
intentionally tiny and obscure. Looks like considerable effort was
made to hide the method of construction. This is the best photo I
could find:
<http://www.permo.no/MFJ/MFJ-1800.jpg>
I can't really see what's going on, much less have enough info to
create an NEC2 model. In addition, I'm more than a little suspicious
of what looks like about 1/2" of exposed coax center conductor at the
center pin of the "N"(?) connector. That's an inductor and radiator,
which are not very clever design or construction.

If you re-read what I posted, you will notice I stated "series coax transformer". An in-line impedance transforming section is totally different to simply stuffing RF choking on the line.

It is the method the three major manufacturers here in Australia employ on their SMD's and the driven FD's on their yagis.

I wanted to know if there was such a radiator in the system that could
do such a thing and apparently there is not! I am working on one that
will do it but I wanted to be sure if I was
not reinventing the wheel.
My antenna is based on using something like a ladder line only with
the wires closer together to provide a lower impedance. If you close
both ends of such a line and wind a helix with it you can get a
radiator beam that will do all the things I suggested except the "all
frequency" part which requires further additions .
If you have two open wires in parallel and slide a cross connector up

and down the two wires the resonant frequency changes dependent on the length where the jumper is.
Thus, if you literally make the ladder line into a true ladder by fixing a lot of conductive cross rungs on the ladder, the applied current will cross over at the point that the circuit is resonant.
This way the radiator will get the "all frequency" attributes.
Such a radiator becomes a much physically smaller radiator than is being used today.
Why not try it.?... It is the proverbial free lunch!

Are you saying a wave on a transmission line will continue to propagate beyond a short-circuit across the line? If so, you've missed something important.

Not sure what you are getting at Chris.
The applied current will travel the 1/2 WL of the radiator/
transmission line and then turn so it will be at resonant impedance at
the input, at the impedance value of the line. The current will not
continue to travel any further than when the closed circuit that is
resonant is reached. In other words, a transmission line can be seen
as having the same impedance or load at each end at a given frequency.
If you close one end, is it not still resonant? If you want to dig
further look at my home page unwinantennas to see where I am coming
from.
This is the same principle used when matching a radiator with
transmission line sections as shown on a nearby current thread (at
least that is the way I see it but then I could still be a fraud by
any other name!) I have done this many times in practice BUT it may
well be the "why's) that I am misinterpreting.
On the other hand I cannot see how a AC circuit wil short across as
you have intimated.
Again I could be wrong as usual! When I model such an arrangement it
provides gain in the order of 10dbi +/- 1.5 db regardless of the type
of radiation that is directed at it. Well one type doesn't work out
well but I don't know where it is usedn in today's world

Hi Chris,

So, you want to turn a massively shorted thin transmission line into a
radiator?

How does the current get past the first short? It cannot, so that
string of shorts up the line are redundant and you can remove them.
This leaves you with a very small loop very close to the transmitter.
Almost every ham has tried working into a short and has never found it
productive. Have you tried it?

A light bulb might work. It will pickup (or radiate) any polarization
type and direction. An unshielded dummy load might also work. It
won't have much gain, but it will meet your criteria for bandwidth and
polarization. It's also kinda cool looking.

>That is made for a single circulation signal only.

It might be done with 4 quadrifilar antennas. Each antenna has a
hemispherical pattern and one sense (left or right hand). With 4
antennas and a suitable combiner, each antenna will cover one half of
the pattern, and one of the two available senses. The quadrifilar
antenna will work with linear polarization, but at reduced gain. The
usable bandwidth is probably insufficient to cover DC to light, but
multiple quadrifilar antennas can be attached to the surface of a
ball, resulting in a sperical pattern approximation and a construction
that looks like a puffer fish. It's also possible to conglomerate the
quadrifiler into a tapered helix, thus increasing the bandwidth at the
expense of gain. For VLF, shove a ferrite rod into the middle.

You can also do random polarizations by using leaky coax, tangled into
a Gordian Knot. Some part of the knot will undoubtably be parallel to
the random polarization, and thus provide some signal pickup. Gain
will be limited by the length of the lossy coax and size of the knot.

Shouldn't you be addressing Art Unwin with that? ... it's he who's proposing
the idea, not me.

Perhaps the behaviour of Outlook Express has led to confusion (again?),
despite my leaving a double line space between the OP and my comment.

Chris

Hi Chris,

I don't know about a double line being a convention for that, but as
you can see above, this time quoting is proceeding as natural.

So, this shorted transmission line is Art's? Has he ever, ever
reported a QSO outside of his zip code?

I'll try to get a better picture of the feedpoint for you.
Is there a way to work the .66 wavelength of 50 ohm cable backwards ie.
What impedance would be transformed to 50 ohms with .66 wavelength of
50 ohm coax?
(this assumes the little knowledge I have about impedance transformation
using
coax is correct.)
Mike

2940. Rebellion on NEC programs

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-08 16:24:50 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <398ea4aa-25ea-4244-9228-dd4cb11dd0d7@w19g2000yqk.googlegroups.com>
Source record: 12152

In the days before NEC amateurs did antenna testing in the field. This
was
a very fruitfull area for the naysayers to argue because the attack on
the method of testing could never have closure and the naysayers with
the loudest voices continued to rein as the true experts with respect
to antennas and amateurs.
Then we had the onset of Mininec and Nec computer programs that
initially
was welcomed with open arms until program discrepancies began to show
up and the naysayers began to rein supreme again. We now have the
instance that programs are downright wrong when they cannot forecast
the shorting actions of electricity with respect to antennas! Since
amateurs are of different backgrounds those not knowlegable of science
will follow the naysayer with the loudest voice who believes as with
pornography new radio science when seen can obviously be recognised as
a bogus technology.
Thus hams who desire smaller and better antennas to use in the
hobby to compete with the bigger and better have no where to go in the
pursuit of the truth other than self satisfaction with their own
antenna set ups in silence, while those with the loudest voices
continue with the mantra that all is known about antennas because the
naysayers volume of denials of the new because of their ability to
recognise fraud when they see it. Now we are at the point where
naysayers have presented the arguement that antennas made of mesh
cannot be used at radiators
while on the other side we have a report that some hams use shopping
carts as radiators while waiting in spacious parking lots.
Now, after trashing the usefulnes of NEC programs by those who
"know" are taking on those whose experience of mesh radiators as being
feaseable who have decided to remain meek and silent rather than face
the wrath of those led by the loudest voice. Now the trend is to roll
back the science teachings of Einstein, Planck and others by verbal
agression so that a new antenna technology can emerge and slaughter
the sciences that some profess to know as "false just by visuallizing"
without the need for thought.
So what does the future hold for those here with an interest in
antennas as the title of this forum implies?

Without calculations, math, engineering, and modeling, you can return
to the days of trial by combat, proof by assertion, cut-n-try, claims
of amazing performance, irreproducible results, witchcraft, magic,
etc.

Granted, there are limitations to NEC2 modeling software.
<http://en.wikipedia.org/wiki/Numerical_Electromagnetics_Code#Limitations>
Rather than abandon years of work simply because you have invented an
antenna that cannot be visualized, optimized, modeled, seen or
demonstrated, a more productive solution to your problem would be to
find (or write) a suitable modeling program that would quantify your
"mesh" antenna. If you find that NEC2 or NEC4 based programs are
unsuitable for your purpose, there may be specialized programs that
may work.

In the mean time those you recognise errant sciences when they see
them dominate over all others who choose not to question their
perceptability of total forsight of what is right and what is wrong.
It is not my problem, as you say, because I didn't write a program
that would win the day, the programs are already there. It is just at
this time the naysayers have the forsight to say what is wrong which
requires rebellion against that which say what is correct.
Personaly I believe there is progress in designing a radiator that
recognises CW and CCW
transmissions that provides choice in selection of what polarization
is used. After all hams wish to communicate with all and have no wish
to be left out because of the poor choice of antenna to use.
For the same radiator to be useable on all frequencies that we
are not licensed to use is purely academic to our interests tho for
the sake of science and the art of antennas the possibilities of what
is perceived to be a discovery should be pushed aside

on the basis of those that recognise what is bad based on what they perceive to have seen.
The real problem today is that what we have accepted as good for antennas ala NEC computer programs is not being accepted as viable by those who have visual forsight that takes precidence over the science of NEC programs and physics of the dayare using the volume level of their voices to persuade all to denounce same.
With this aproach being gradually accepted by those who remain silent we are being pushed back to personal antenna measurement which allows for assertions of incorrect use of testing which in effect gives credence with hams that for antennas all is really known! After all, it suggests that if mesh radiators were able to transmit all amatuers would be using them, when they are not! Thus the naysayers with undeniable visual forsight must be correct!
So now amateurs are on a roll having "proved that short circuits occur when using mesh via naysayers from both sides of the pond, who can now dismiss with confidence the demise of helical antenna design change having convinced all that NEC programs have now been shown as defective. Next the idea will prevail that sunspots are there in abundance but cannot be utelized while hams continue to use radiators that naysayers, using the same "ability to recognize pornography" when "they" see it, use the same abilities
to recognise psuedo sciences to deny those that pursue experimentation to achieve the
possibility of advances in the hobby.
Now it is labelled "my problem"..... (Yes Aussie, I am the ART that they usually attack), as it was for all the previous knowledgable hams with respect to science and antennas that fled rather than argue with those that belong to the "no" group which have the louder audibles that rule this group.

Hi Mike,

That is a pretty good rendering given the other pix. Have you any
experience with Smith Charts? Still, and all, you need to know the Z
of at least one point to transform to another.

There are many antennas that discriminate between polarizations.
Satellite antennas often have CW or CCW switchable polarizations.
There used to be some 11m beams that had vertical, horizontal, or
circular selections. It is relatively easy to do vertical/horizontal/
cw/ccw with a pair of crossed yagis or just crossed dipole elements
and 1/4 wave phasing lines.

You moved resulting in the one area of interest, near the coax connector, being difficult to see. Can you try again, this time not moving? Extra credit for putting a piece of graph paper under the antenna so I extract dimensions.

The point I was trying to make is that the fairly long and exposed leads at the connector, are perfectly acceptable for low frequencies (HF) but are NOT acceptable for microwave work at 2.4GHz. The exposed wires are inductors and/or radiators. My guess is there's a total of about 4mm of exposed conductor. With a wavelength of 12.5mm, that's 1/3 of a wavelength. Before hitting the balun (or whatever that's suppose to be), most of the RF will be radiated by the exposed section of the coax, not the antenna.

I'm not an expert on baluns, but that thing doesn't look right. The coax cable forms a balun, but the ferrite cores aren't involved except to do block any RF coming back along the outside of the coax. My guess(tm), is that the designer attempted to design the folded dipole feed for 50 ohms, but discovered that the VSWR was far too high. So, rather than move the feed impedance up to the more common 200 or 300 ohms, and use a 4:1 balun/xformer, he just shoved a bunch of ferrite beads around the coax in order to "fix" the VSWR problem. It's not really fixed or even matched. It just doesn't show any VSWR. The real VSWR, measured at the feed point, is probably quite high.

>> Is there a way to work the .66 wavelength of 50 ohm cable backwards ie.
>> What impedance would be transformed to 50 ohms with .66 wavelength of
>> 50 ohm coax?

50 ohms. If the source, load, and coax are all 50 ohms, then there's no transformation. You can use any length of 50 ohm coax and it will still be 50 ohms in and out. Of course, we're assuming that the MJF-1800 uses 50 ohm coax, not 75 ohm, which would be another story.

>> (this assumes the little knowledge I have about impedance transformation
>> using
>> coax is correct.)

One must suffer before enlightenment. Let's pretend that it's 75 ohm coax instead of 50 ohms. Let's also ignore the sloppy exposed conductors at the RF connector. Let's also assume that we don't really know the impedance of the folded dipole fed antenna. Unfortunately, I also have to assume that your 0.66 wavelength doesn't include the velocity factor for the coax making it closer to 0.75 wavelengths (so I can do this without dragging out the Smith Chart). Odd multiples of 1/4 wavelength will neatly transform the endpoint impedances according to:
Zcoax = sqrt (Zin * Zout)
or
Zcoax^2 = Zin * Zout
So, with a 50 ohm load, 75 ohm coax, and 3/4 wavelengths of coax:
Zout = 112.5 ohms
which is a bit closer to what I would expect to see with a folded dipole antenna.
<http://www.antennex.com/preview/New/quarter.htm>
The designer could have also done it with 93 ohm coax, but the photo doesn't look like RG-62/u. However, if he had, it would transform to 173 ohms, which is quite close to a folded dipole.

Bottom line.
I'm not thrilled with the design or construction of the MFJ-1800.

They should have been better, those are pictures I took a couple of years
ago.
I didn't blowup someone elses pictures.
Re: "you need to know the Z of at least one point to transform to another."
I would be happy with the assumption the the impedance at the N connector
is 50 ohms. But I think I have a misunderstanding because, in use you would
add more 50 ohm coax to run from the N connector to the transmiter. Soo,
that .66
wavelength section on the antenna becomes anything you add to it.
AT this point, I have to think the folded loop is forced down to 50 ohms by
it's
surrounding structures and there is no impedance transformation betwen the
loop
and the N connector.
Mike

I intentionally left out religion, congressional action, hucksterism,
fluoridation, and collectivism from my list of what might happen
without proper antenna calculations. These are all functional
alternatives to doing the numbers, but also have serious social and
political difficulties.

Also, there is religion in ham radio. Once a year, during the last
weekend in June, a horde of antenna worshipers ascend to the nearest
mountain top and erect monumental temporary altars in an attempt to
communicate to the radio gods their petition for more sunspots and
"good DXing". For an entire day and night, this horde will feverishly
"pound the brass" and "eat the mic" to noisily waken the radio spirits
and thus hear their petition. Yes, ham radio has religion.

Ok, let me try again, this time while not talking on the phone, eating
lunch, and watching TV.

One wavelength at 2.4Ghz is 12.5cm. Guessing from the photo, there's
a total of about 15mm of exposed conductor. That's about 1/8th
wavelenth, which will still radiate rather badly, but not as badly as
I previously erroniously assumed.

> In the days before NEC...

Note that NEC uses the research and equations of "The Masters" that (allegedly) you revere, Art -- and which have proven valid and useful for many decades prior to the appearance of NEC.

Computers using NEC software make it easier to apply such equations. But accurate results when doing so require that the NEC software is well understood, and properly used for the system being modeled.

The accurate understanding, and proper use of NEC leads to valid conclusions about antenna system performance.

Assuming the radiator is actually resonant then the vswr doesn't really
matter but as you point out the exposed centre conductor will radiate
badly and certainly not a design to be emulated by effectively stopping
the reflected rather than matching correctly .

I did figure in VF so .66 the proper figure to use. I know, both .66
but that was a coincidence, just the way the numbers crunched.

50 ohms! No impedance transformation would occur.

Is that what I was doing last field day. I could have sworn I was
putting up two jack up masts with commercial triband antennas on them
to practice radio in the field and have a little fun. How do I go
about getting my congregations ministry and worship committee to
except it as a religious retreat. The fact that we had a no alcohol
field day would get me part way there but antenna worship might come
across as idolatry to the more straight forward practitioners of more
traditional forms of religion. That brings up another item of faith.
I thought that the Amateur Radio Code specifically banned discussion

of religion via amateur radio. I take it you don't believe that simple courtesy should apply to off the air discussions of amateur radio. It's all good though you can just have the state militia band play drums around the scaffold so my heresy cannot be heard when you hang me for being the wrong religion. That worked for the puritans in Boston low these many years ago.

Another thing to note: based on the pictures posted today, the DE isn't all that close to being a classic folded dipole, with close-spaced segments. The segments are much more widely spaced... it looks to be about half-way between being a folded dipole, and a one-wavelength loop such as might be used in a Quagi design.

This is going to significantly change its free-space impedance, I would think. An FD would be around 300 ohms, a one-wavelength circular or square loop would be somewhere in the general neighborhood of 100 ohms.

This DE may not need as much impedance transformation (from coax) or proximity reduction (e.g. from a reflector and one or more directors) than a classic FD would, to achieve a decent match to a 50 ohm coax.

Dave
Please forgive my ignorance but for the sake of my education would you
flesh out number three some more. We used a four square for the 2008
field day and I watched the construction process very carefully but I
don't recall what kind of seventy five ohm coax we used. Does using
foam coax bring the velocity factor closer to one so that the cable is
thus longer. I don't remember having any problem with the cable
lengths but I freely admit I was functioning as labor rather than
design or supervision. So maybe that had all been worked up in
advance so those of us assembling the antenna didn't have to cope with
it. I might well be putting my lack of education on display by asking
this but it is the only way I will learn. Could you not use the right
multiple of quarter waves and thus get the length you need with any
seventy five ohm cable? I realize we would have increased the
transmission line losses but would it be enough to be significant on
say forty meters. That's what our four square was built for. When we
were testing it weeks ahead of time it appeared to perform very well.

We got at least two S units better signal reports when compared with a
single vertical.

cm and mm if possible. The reason I suggested graph paper is that I
can usual compensate for parallax with graph paper, but not with just
a ruler.

<http://s395.photobucket.com/albums/pp37/Qmavam/>

Much more better photos. Thanks. However, I can't measure the length
of the coax "balun" with any of those pictures. I would like to check
your calcs for the 0.66 wavelengths, especially since I don't know
from where to where you measured. (Hint: from coax shield to coax
shield. Everything else is a radiator and/or series inductor).

You forgot to list one:
<http://s395.photobucket.com/albums/pp37/Qmavam/MFJNconnector.jpg>
That's 6 mm of exposed center conductor (including the center pin)
plus more at the ground lug (under the ruler). Guessing some more...
A 1mm dia wire, 6 mm long = 3.0 nH.
<http://www.consultrsr.com/resources/eis/induct5.htm>
At 2.4Ghz that's
XL = 2PiFL = 2 * 3.14 * 2.4*10^9 * 3.0*10^-9 = 45 ohms
of series reactance. With a 50 ohm "load", that's not going to help
make a very good match.

Modeling asymmetrical Yagi elements is not my idea of fun. I should
learn how to do it since I designed a similar sheet metal stamped Yagi
for 900MHz in about 1983. However, that was done with guesswork,
cut-n-try, a bit of plagiarism, and lots of midnight snarling.
Incidentally, to improve the bandwidth, it would have be trivial to
round off the ends of the elements. There are also some rather odd
effects caused by the width of the "boom", which doesn't follow the
usual round boom Yagi model. Oh well.

I can't find a photo of my stamped metal Yagi, but perhaps a
description might be interesting. I mounted a right angle N coax
connector centered on the "boom" at the driven elements and facing
towards the reflector. The driven elements were also stamped
aluminium. I used a gamma match consisting of a piston trimmer cap
mounted on one of the drive elements, and a heavy copper wire from the

cap to the center pin of the N connector. That was covered with a
clam shell plastic radome.

Wrongo. VSWR does matter. VSWR is a measure of impedance matching.
Failure to match impedances means that your antenna is no longer
working at the optimum power transfer point (i.e. maximum efficiency).
It will still work with a high VSWR, but not as well. High VSWR also
has highly undesirable side effects such as, mangled gain pattern,
radiation from undesired conductors, loss of gain, and loss of
efficiency. Resonance is a good thing, but not absolutely necessary
for proper operation. Resonance would be where the reactive
components are zero. Since I don't see any adjustment(s) to tune out
(resonate) the inductances introduced by the relatively long exposed
coax leads, I don't think this antenna is particularly close to
resonance.

>but as you point out the exposed centre conductor will radiate
>badly and certainly not a design to be emulated by effectively stopping
>the reflected rather than matching correctly .

Yep. It's like fixing the symptoms rather than fixing the source of
the problem.

This is very problematic.

High SWR may be a product of unintended radiators (like the pigtail
going from the choke bead to the feed point), but far-field radiation
lobe pattern shape is NOT affected by SWR due simply to mismatch.

There's a lot going on in that statement, so I'll try it again this
way:

Added, unintended radiative elements cause mismatch AND pattern
distortion AND gain reduction (to the degree of mismatch). This is
the basis for concern about the pigtail.

A perfectly implemented design that presents an Z other than that
expected (mismatch) causes gain reduction (to the degree of mismatch).
The pattern's shape is not altered except that its gain values at any
angle are depressed equally by the degree of mismatch.

Resonance is desired for match AND efficiency.

Going further:

The degree of pattern distortion is a complex function of this
additional pigtail radiator. There is every chance that it won't
perturb the pattern much unless you are very concerned about nulling
out interfering sources. It probably won't affect the match much
either as the driven element Z will probably swamp out the
contribution from the pigtail Z.

>Is that what I was doing last field day.

Possibly yes. The reason behind Field Day and the origin of the term
"ham" have been lost to antiquity. In the past, they had some
meaningful purpose, but over the ages, all we have left is the ritual.
At some point, there possibly was a real and useful purpose to the
ritual of climbing mountains, erecting antennas, and chanting arcane
acronyms and cryptic abbreviations into the radios. As with
archeology, anything that cannot be explained is automatically
attributed to a religious purpose. Archeologists have excavated many
a brothel and erroneously proclaimed it an ancient temple. So it is
with Field Day. Lacking a suitable alternative explanation for such
unproductive and irrational behavior (other than mass insanity), the
only logical purpose for Field Day can be religious in nature.

>I could have sworn I was
>putting up two jack up masts with commercial triband antennas on them
>to practice radio in the field and have a little fun.

If you were having fun, it is not religion. Religion requires
suffering. In future Field Days, I suggest you attempt something more
ambitious, such as running on bicycle generator power. That should
make it a real religious experience.

>How do I go
>about getting my congregations ministry and worship committee to
>except it as a religious retreat.

You can't. Established religions do not recognize pagan rituals and
derivative practices. I'm afraid that Field Day apparently had its
origins in the former, which are an anathema to the established
religions. The only reason there hasn't been a crusade against ham
radio and its Field Day ceremony is that much of the symbology is
similar to those of the established religions. Next time you erect a

mast with cross arm, ask yourself of what it resembles.

>The fact that we had a no alcohol
>field day would get me part way there

We tried a 50-50 alcohol gasoline mix in the generator. Bad idea.

>but antenna worship might come
>across as idolatry to the more straight forward practitioners of more
>traditional forms of religion.

I don't think that will be a problem. For example, I offer a silent prayer every time I use the ATM banking machine, hoping there will be some cash left in my account. Yet, nobody has accused me of worshiping the ATM banking machine. Similarly, nobody has ever suggested that you are worshiping your radio or antenna. Well, maybe the Collins S Line collectors may be an exception. As long as the radio deity is invisible, uniformly distributed through the cosmos, and can survive an audit, there shouldn't be a problem.

>That brings up another item of faith.
>I thought that the Amateur Radio Code specifically banned
>discussion of religion via amateur radio.

Well, perhaps religious discussions using code may be banned, but I don't recall any such thing for other modes. Little wonder the FCC dropped the code requirement. I've often suspected that the original founders of ham radio were all attorneys, since possession of a ham license also seems to entitle one to offer legal opinions and interpretations.

>I take it you don't believe that
>simple courtesy should apply to off the air discussions of amateur
>radio.

Yep. I prefer complex courtesy. The problem with most over the air discussions is that it's impossible to have a discussion, simple or otherwise. The cause is also lost in antiquity. At some point in the distant past, it was necessary to repeat ones transmission several times due to interference, fading, and static. This was probably the case with spark gap (the original broadband initiative). Like Field Day, the purpose was lost in antiquity, leaving use with long winded blow hards repeating themselves endlessly. Unless you want to engage in multi-hour long conversations, the average conversation more closely resembles a monolog. It's really difficult to be discourteous if the listener has gone to watch TV waiting for their turn.

The problem was recognized long ago. The answer is contesting. The contesting solution resulted in the opposite extreme. A conversation consists of call sign, signal report, and some trivial identifier. Courtesy and contesting are oxymorons, as it's almost impossible to win a contest by being courteous. The exercise sounds more like jamming than discourse. Contesting is not a solution to the courtesy

problem.

The digital modes have their own answer. Most conversations are computer to computer. The dialogs are canned and carefully word processed into political correctness. I don't know anyone that has insulting macros saved in the PSK31 program. Digital modes have simple courtesy, but also kinda dry conversations.

>It's all good though you can just have the state militia band
>play drums around the scaffold so my heresy cannot be heard when you
>hang me for being the wrong religion. That worked for the puritans in
>Boston low these many years ago.

That used to be the case up to about 10 years ago before cable TV, satellite TV, and CC&R's. Operating during prime time would result in the neighbors organizing a torch light parade to your doorstep, complaining of TVI, and offering to lynch the offender by his own antenna tower. I think you're fairly safe today, especially with todays QRP radios, which can easily be hidden when the torch light parade arrives.

Groan. Now, where did I screw up?

>High SWR may be a product of unintended radiators (like the pigtail
>going from the choke bead to the feed point), but far-field radiation
>lobe pattern shape is NOT affected by SWR due simply to mismatch.

Agreed. However, I was thinking that the added inductances at both
ends of the coax are going to mangle the function of the balun, which
will create pattern changes.

>There's a lot going on in that statement, so I'll try it again this

Yep.

>A perfectly implemented design that presents an Z other than that
>expected (mismatch) causes gain reduction (to the degree of mismatch).
>The pattern's shape is not altered except that its gain values at any
>angle are depressed equally by the degree of mismatch.

Well, I previous guestimated that the 6 mm of exposed center conductor
at the coax connector was good for about 3 nH or about 45 ohms at
2.4Ghz. If the balun represents 50 ohms from the antenna, then the RF
power is roughly split evenly between being radiated by the 6 mm

"leak" and going to the antenna or connector. Its close proximity to the driven element and reflector suggests that there may be considerable re-radiation.

(I'm resisting the temptation to borrow or by an MFJ-1800 antenna and bench test it.)

True if the "leak" is far away from the driven element. In this case, it's fairly close. I would expect some coupling and therefore some pattern distortion.

>It probably won't affect the match much
>either as the driven element Z will probably swamp out the
>contribution from the pigtail Z.

45 ohms reactance in series with the antenna is certainly going to do bad things to the VSWR. For it to be at resonance, there has to be a tuning cazapitor in there somewhere to tune out this added inductance.

Good point. It does look a little on the short size for a folded
dipole. I also noticed that there's a plastic insulator at the
midpoint of the driven element. The midpoint can be at ground
potential with either a folded dipole or full wave loop, but this
design goes out of its way to use an insulated spacer. The only
reason I could think it would be necessary is if the balun isn't quite
balanced and grounding the midpoint sorta fixes half the driven
elements mismatch.

This is how a typical 1 wavelength loop Yagi driven element is usually
built:
<http://www.directivesystems.com/loopyagi.htm>
Notice the lack of a balun, exposed wires and ferrite beads.

>This is going to significantly change its free-space impedance, I
>would think. An FD would be around 300 ohms, a one-wavelength
>circular or square loop would be somewhere in the general neighborhood
>of 100 ohms.

Well, the wire length of a full wave loop and a folded dipole are
roughly the same. The way a folded dipole works is that you start
with a 1/2 wave 72 ohm dipole. Adding the extra wire creates a 4:1
transformer, resulting in 4*72 = 288 ohms.
<http://www.qsl.net/w4sat/fdipole.htm>
Take the same folded dipole and spread the 4ea 1/4 wave sides into a
square or circle, and the impedance changes to about 100 ohms. Off

hand, I would guess that the MFJ-1800 DE is about half way in between
a folded dipole and a loop at perhaps 150-175 ohms.

>This DE may not need as much impedance transformation (from coax) or
>proximity reduction (e.g. from a reflector and one or more directors)
>than a classic FD would, to achieve a decent match to a 50 ohm coax.

Agreed. The question of the moment is whether the MFJ-1800 balun is
50, 75, or 93 ohm coax and its length (shield to shield).

Hi Jeff,

Actually, the inductance is shunt, not series to the drive. Look at
the drive point connection and you will see the shield/center open up
with very little dressing needed, basically that span fills the loop
creating a virtual drive point at the end of the braid. At that point
looking back towards the beads is where the shunt reactance lives.

As for its contribution to skewing the pattern, that is a function of
the match to that shunt section, and its radiation resistance.

No doubt Roy will chime in if I've jumped the tracks here.

>True if the "leak" is far away from the driven element. In this case,

Coupling is certainly a confounding factor to my explanation above.

I remeasured the coax, (shield to shield) it is 2.135" long.
The length of the Loop is 4.85"
Got a little hurricane coming our way, need to take care
of the boat and business today. Need to drive 9 hours Tuesday,
then again on Wednesday. I hope to get dimensional pictures
posted on Thursday or Friday.

Hi all,
I'm looking for the instructions manual of the "Remote Programmable Antenna Rotator AR500". I bought one at a local 2nd-hand-ham-market but I can't use it without the manual.
Has anybody a scan of it ? Or does anybody know a link to download it?
I would be very gratefull if I found any help !
Thanks a lot in advance

the cable i normally use is rg-11u with foam dielectric, that gets the
velocity factor up to .78-.80 so the cable is longer to get the
required 1/4 wave. since the distance from the center to the corner
of a normal 1/4 wave spacing 4-square is .707 of a wavelength the
normal hard poly with a .66 velocity factor won't reach.

What the heck is this all about, I thought Art was going to rant about
how hams just sit around and model antennas and never actually build
them. That would have been funny.

Consensus of the group say RF applied to a mesh will short or fuse.
NEC shows that it will not and that it will radiate.
On my home page I did the same thing and got an SWR curve
Therefore Art and NEC programs have got it all wrong.
This probably means that a faraday shield will short also, but that
needs a little more
consensus from the group as it would destroy the shielding of the
innards.
Therefore the NEC programs must have it all wrong!

Dave
So my guess was close but what about the rest of the question. Would
any odd multiple of a quarter wave work as well except for the
transmission losses it would introduce? Would three quarter waves
work?

Art, did you forget about the NEC analysis linked below?

How much will your mesh antenna radiate, unless you have invented a
VERY heroic network to match it to typical transmission lines
(comments, please)?

http://i62.photobucket.com/albums/h85/rfry-100/Arts_Mesh_Antenna.jpg

Actual mesh used by Art
Aluminum mesh, windows, insects
Wire dia .011", mesh 18 by 16
Per group analysis, wires will short.

Your analysis, shows it radiates
physical measurements of Art, shows radiation.

Conclusion
NEC faulty per the groups teachings
Art's actual measurements also false
per groups teachings

Future actions suggested
Repeat NEC with actual mesh sample measurements used.
Show mesh circuit currents
Apply RF to outside of actual faraday shield and document results.

i 'think' so. since it adds an extra 1/2 wave delay to each of the
elements and should result in the same impedance transformation it
should work ok. it may be a bit more narrow banded since the
impedance transformation would change faster with frequency, but
probably not enough to notice.

Being able to pick up only 'snippets' through the stovepipe, it would
seem that Art either damns or praises NEC according to the wind
blowing to his detriment or to his favor.

If there were any dispute with the "consensus" it would seem to be
simple enough to contribute engineering evidence rather than religious
testimony. Art recites NEC, but I don't see (and that is possibly due
to filtering of static) any NEC content in the fragments of Art's
hymnals that survive through to the willing suspension of disbelief.

W'ot? Ain't I demonstrandum? (the alpha and omega of Art's
intellectual proofs).

Art, you are going to need at least two more criminals up there on
calvary before you can draw a crowd of legionaries to throw dice at
your feet.

Well that's the end of this thread! Clark and his followers now appear
to be moving towards accepting NEC and also that mesh will radiate
according to the physics portion of his degree in literature(assuming
he is following the teachings of physics that is extensively
used in literature and shakesphere) with honors for showing he
had no balls when dancing in mesh tights at his hide out! It would
appear that the group is in disarray over whether Clark is to be
followed with respect to R.F. having the same characteristics of D.C.
current when applied to a mesh conductor. When you all make up your
minds whether a mesh radiates or not. let me know so I may use it or
discard it to satisfy the group. Since R.F.what ever his name is
intent on desception by suggesting that window mesh wires to keep
insects out are 0.5" apart in mimicing my findings there is no point
in responding to him anymore with his trash in the future. As for
religeon, you will make no friends by encouraging others to forsake

their religeous faith in favor of homosexuality.

Then tell me. Do you agree with Clark and others that RF applied to a
mesh will short out at the first square of the mesh or not?
This is for discussion of antennas by the so called experts to educate
those who enjoy the hobby. You say that you have extensive experience
with antennas! So share with others your opinion whether a mesh screen
will radiate or not , and move away from your nonsensical attacks on
others and share your extensive experiences which you always shy away
from. If you move away again from antennas to vent your internal
feelings the thread will die whether you like it or not, as others
will move away from such response postings. Sooner or later you will
have to verify your expertise with antennas instead of constantly
wielding the knife, instead of contributing to the newsgroup with

respect to antennas. You called me "sick" and I respond with say "you are a female impersonator"
You then come back with another rabid comment and so on. Is that what you want for the group? If so, there are some here who will probably join you since they are natural followers. In no time you can then join those that decry religion and thus you will be in your comfort zone if that meets your needs.
Antennas or slander, where do you want to go?
A group of hams have declared that mesh will fuse and will not radiate. This is contrary to NEC teachings so what shall we believe, NEC or the opinions of this group?

A group of hams have declared that mesh will fuse and will not radiate. This is contrary to NEC teachings so what shall we believe, NEC or the opinions of this group?

** New posting, not from the previous author Art Unwin (clear enough?). The author of the previous post apparently forgot to sign his name.

Art, you must be applying EzNec, or whatever it is you use, beyond its capabilities. As I wrote several days ago, if you believe an EM wave travelling on a transmission line (in a normal transmission-line mode such as a TEM wave) can propagate beyond a short circuit between the conductors of the line then I think you are missing something rather important - like Ohm's law!

Some clever antenna designs make use of a short across a line to reflect the differential-mode wave (in order to improve the match) whilst allowing propagation of a common-mode wave beyond it (in order to increase the effective length of the driven element). However, it would be difficult to apply this to a piece of mesh - lots of inter-node links would need to be cut. At the end of the day, almost anything can be made to radiate, inefficiently though.

** This post from christofire@btinternet.com , not Art Unwin (clear enough?).

** additional posting from christofire@etc., not from Art Unwin.

I just wrote 'Art, you must be applying EzNec, or whatever it is you use,
beyond its capabilities' but it could be simply that you are
mis-interpreting the results it gives. Richard Fry's effort at
http://i62.photobucket.com/albums/h85/rfry-100/Arts_Mesh_Antenna.jpg
suggests a VSWR approaching infinity - what VSWR did your model give for a
shorted transmission line of small length?

No such consensus that I am aware of . It could behave in many ways
depending on geometry, frequency, size. I have a slot antenna that
could be described as such. I doubt if anyone here would claim that it
will short or fuse.

Well you started all this but never explained your position so Clark
entered the picture with his interpretation of physics which appeared
to match yours.
Ohms law is fairly short so explain your position.

>
> Some clever antenna designs make use of a short across a line to reflect the

Yup you need a more expensive program to do it. Eznec wont do it.
You will need a lot of segments. Of course you can measure it if you
have a sample and a MFJ259b like I did.

 At the end of the day, almost anything can be made to radiate,
> not very efficiently tho.

Hmm, mesh allows the displacement to be broken up into parts which
allows for the intersection of two fields to create radiation by
particle levitation where as your way you would disregard the enclosed
particles by the displacement current so you can state a wave floats
away for propagation

>Any thing can radiate

Very true unless, as Clark states, a direct short results and that is stupid. But he likes to mislead others into agreeing with him. Then on insults start and we are again at that point.

Art, you've obviously forgotten that YOU started this thread.

Get meds, you need them.

>
> ** Chris (again)

Look at my page ! I measured it! See for yourself.
Should I ignore actual measurements ?
Fri didn't show all the data used, but he DID falsify the distance between wires which has a direct bearing on impedance/ VSWR ? Not only that, we only have his word that he used a program with enough segments to model the same sample that I measured.
As for my modeling I never did one for a shorted transmission line. I can tell you, that I will model a ribbon style helix antenna as shown on my page and I will present it for all to see. You may then comment why it is in error per the groups interpretation. That is basically a shorted ladder line which is being used as a radiator which apparently you are looking for. The cross bars will simulate a ladder line where it got wet which reduced the effect of the insulation dependent on the frequency applied.This allows the displacement current to deploy earlier than intended by the design and thus radiate. Discuss with your physics friends or just rely on Clark;'s antics.

I don't know. I was comfortable with NEC until Clark stated it was
producing incorrect answers i.e. it shorts so it cannot radiate, It
seems that the group agrees with him.
Must I now throw my antenna programs away to abide by the majority of
the experts?

Yes idiot. I started it after Clark made an observation and the group
agreed with him.
I am not willing as yet to discard NEC just on his say so.
Are you? Why?

OK Tom
I called you an idiot in return last time.
This time I will ask if you ever perseuded your wife to
come back home after your last augument? Why is she refusing?
You sound lonely.
Are you and I going to take over this newsgroup from now on?
You insult and I insult in return?
What are the limits on the type of insults before the cannons come out?

Heh. If you can't be bothered to read it in the first place
then you surely will not read a quote. Did you ever graduate from high
school?
What did you graduate from next? I know, you have never responded on
that to others.
Why did you beat your wife in the first place that made her leave?

>> Have you plonked Clark?

What a curious complement. I have "plonked" Art, and it has reduced screen clutter other than that which survives quotation (fellows, you really need to learn selective quoting - wading through his rambles returns that tedium by proxy).

In the world of physics that goes to particles, photons, the weak force, and so on, there is a branch that takes on "strange attractors."

I wonder what force restrains Art from "plonking" me?

I happened upon a recent incident in Soccer that had a youtube commemoration of a thrashing (those girls show more muscle than Art) set to a song by Drowning Pool:

Let the bodies hit the floor
Let the bodies hit the floor
Let the bodies hit the floor
Let the bodies hit the floor Beaten why for
Can't take much more
One - Nothing wrong with me
Two - Nothing wrong with me
Three - Nothing wrong with me
Four - Nothing wrong with me
One - Something's got to give
Two - Something's got to give
Three - Something's got to give
Now
Let the bodies hit the floor
Push me again
This is the end

Kind of repetitive. Lots of anger. Cogent self analysis. More repetition.

And it is rebellious.

Well, I don't expect any NEC file (damned if you do, damned if you don't - had to keep the religion in it).

> Richard,
>
> You forgot metaphysics.

Like EM. Look at this:

See:
http://www.electronics.radiouk.com/equip/antenna/reflect.php

"Standing wave.
When energy is reflected back towards the source, the combination of the
forward and reflected signals create a third wave. The picture on the right
is a rough demonstration of the creation of a standing wave.
The forward signal (black) combines with the reflected (blue) to create the
standing wave (green) which, although stood still, is continually varying in
amplitude."

It means that at the end of an antenna the voltage is doubled (the same take
place in a capacitor).

Now see at this: http://en.wikipedia.org/wiki/Kundt's_tube
"The sound generator is turned on and the piston is adjusted until the sound
from the tube suddenly gets much louder. This indicates that the tube is at
resonance, which means its length is a multiple of the wavelength of the
sound wave. At this point the sound waves in the tube are in the form of
standing waves, and the amplitude of vibrations of air are zero at equally
spaced intervals along the tube, called the nodes."

Between the nodes are places where the amplitude is doubled.

Derive the voltage doubling from EM.

> As for my modeling I never did one for a shorted transmission line.

Art, are you thinking that if you put a short circuit across the output connector of your HF transmitter, it will not be affected -- as the short is not located one wavelength or some other length from the source?

If so, please invoke your self-stated spirit of experimentation by doing so, and reporting back to us with the result.

For those not so adventurous, the link below leads to a NEC analysis that should be of interest. Note that zero current flows past the first short in the line.

Art - consider how the result of this NEC analysis affects your concepts about a mesh antenna (no matter what the grid spacing).

>Then tell me. Do you agree with Clark and others that RF applied to a
>mesh will short out at the first square of the mesh or not?

The correct answer is maybe. The characteristics of the intersection
of any two wires in the mesh can be dynamically inconsistent. At any
time any junction might act as an insulator, a conductor or a
semiconductor.

It would be wise to understand the materials you're working with
before making any grand assumptions. If any two intersections in a
mesh can have different characteristics, any piece of "identical" mesh
will be different from its model. Such differences will make it
impossible to create reproducible results.

As a side note, last night I won my clubs "weird antenna" contest with a
2 meter vertical dipole made from Jello! (this is not kidding)

Top half was Orange Jello - with a little salt added, bottom half was
raspberry Jello and some salt.

Now on to the NEC issues. There is no doubt that in certain applications
or antennas that NEC will have some problems in calculation.

It is doing a service to the discipline to point out these special cases.

But that doesn't mean that NEC is invalidated because of those cases.
Just means some fine tuning is needed.

I don't get too excited about antennas until they are built. Simulations
are not the end product.

Yes that is correct, the same goes with any radiator or antenna

>

> impossible to create reproducible results.

Well it wasn't a "grand assumption.) To remove the "maybees" that you
refer to you, use as a sample a stretched lath or a multi perforated
sheet of aluminum from the local hardware store
If you are uneasy about using mesh then weld the intersections using a
car battery set up.
or buy a welded shopping basket and play with that to duplicate
reports. Imponderables are always best removed before
experimenting. You can buy sample sheets of different types of mesh
with different types of materials, weave or otherwise on E Bay but as
always
mesh types have to be cleaned of coatings and less so for perforated
forms. The graphs pictured on my page were of these types and the
curves shown are on site measurements.
As always trust in computer programs but always verify.

3030. mast position when mounting a beam?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-11 15:06:31 UTC
From: Steve <zarco@sonic.net>
Message-ID: <4afad2fc$0$1639$742ec2ed@news.sonic.net>
Source record: 12142

I'm in the process of putting up a 4 element 6 meter beam.
I'd like it to be balanced but that means I'll be attaching
it to my pole half way between the driven element and
first director. This is a 2" diameter aluminum pole and I'm
concerned that it will interfere with the pattern.

Can anyone say (with some level of confidence) if this is
a problem? Normally, beams seem to be mounted adjacent
to an element. TIA

Steve

If the pole is perpendicular to the elements it shouldn't have much effect on the pattern or the match, but if you want vertical polarisation then you'll have a number of issues to contend with - the feeder as well as the mounting pole.

Chris

Assuming that it's going up horizontally polarized and that the pole is vertical, it won't make any difference where you put it.

from http://unwinantennas.com/:

"The Sun is very hot because it is burning. Burning as we know it
produces soot and other by products in abundance that when these
particles collect in the air they become visual to the eye as smoke
even tho the particles themselves are invisible to the eye unless
there is a contrast in light as with particles passing thru a shaft of
light thru a window."

Does the author not understand the difference between fusion and
combustion? Why would anyone pay attention to such an ignoramus when
he writes about antenna theory?

Steve,

One thing I found out AFTER I'd put up my HF beam is that 1) I'd mounted the beam too close to the tower, abt 4" - just enough to clear the tower, or 2) I should have located the top egg insulators on the guy wires right next to the tower instead of 3-5' below. Methinks the guy wires at the top of the tower may be resonate on 10-15 meters and raised the SWR being so close to the HF beam. I also put VHF/UHF beams on top of the mast about 3' above the HF beam but their SWR is a very wide band 1:1. If I had to do it over again I'd use a longer mast, which I could have done since the lower part of the mast is secured at least 3' below the rotator bushing.

He makes a good point. I was responding only to the antenna elements,
boom and mast. The environment surrounding it needs to be reasonably
clear, and that includes height above ground.

It appears that, for that Prudential commercial, the
spacing between the dahs is longer than the spacing
between the dits.

3047. Folded Dipole Calculator Help

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-14 18:05:21 UTC
From: amdx <amdx@knology.net>
Message-ID: <d3a46$4afef16c$18ec6dd7$10181@KNOLOGY.NET>
Source record: 12059
Cross-posted to: rec.radio.amateur.antenna,alt.internet.wireless,sci.electronics.design

Hi All,
I'm having a disagreement about the use of this folded dipole calculator
impedance calculator.
http://www.k7mem.150m.com/Electronic_Notebook/antennas/folded_dipole.html
We are using it to calculate the impedance of folded dipoles to drive a
yagi.
When entering data it asks for "Simple dipole feed impedance (ohms)"
Default is 72 ohms. This assumes a 1/2 wave dipole.
The fellow I'm disagreeing with say's,
"the reason that the variable in the calculator for the "dipole feed
impedance"
could be if you want to transform the z to something else, such as 50 ohms."
I don't even understand what he means.
I can only think of one reason to alter the 72 ohms, that would be if you
use a a different length folded dipole.
I'll readily admit the other fellow knows more about this than me, but
I need more convincing :-)
Can anyone explain this to me.
Thanks, Mike

Hi,
The eq. seems right. Folded dipole is basically a loop.
Usually we use 300 Ohm feeder.

Hi,
And you can use a tranformer 300 Ohm to 75 Ohm to use coax if need.
It becomes a from 300 Ohm balaanced to 75 Ohm unbalanced feed.

The way I read it is that you put in the feed impedance that a similar-
length plain-ol' dipole in the same situation would have. In a Yagi this
can be significantly lower than 72 ohms, which is the whole reason you're
considering a folded dipole.

Does the author have contact information? Perhaps you could ask the
source?

I've seen older Yagis that use folded dipoles, but the newer ones seem to lean more toward gamma or T matches. You get more latitude for adjusting impedance, in the gamma case you get a kinda sorta good match to coax without a balun, and if you're employing plumber's delight construction it's no more difficult to fabricate than a folded dipole.

So why a folded dipole, pray tell?

Your statement:
The fellow I'm disagreeing with say's,
"the reason that the variable in the calculator for the "dipole feed
impedance"
could be if you want to transform the z to something else, such as 50 ohms."
I don't even understand what he means.

My thoughts: My radio output impedance is 50 ohms, for a feed line I use
RG-8 and other 50 ohm impedenance coax.
If I were to use a folded dipole antenna I think I would prefer one that had
a 50 ohm feedpoint.

Excuse me, but what does such simple dipole calculator have to do with the calculations for a Yagi feed element ?

Even assuming a single element feed element antenna, playing with the tube diameter (upper and lower bars) or the number of bars in a folded dipole will radically change the feed impedance.

Paul

I think it all started with the MFJ-1800 that uses a folded dipole, but
there
are many yagis that use a folded dipole as the driven element.
But, I think (now) I understand enough to know why you ask the question.
I think your point is the impedance of dipole feed on a yagi is highly
modified
by the reflector and directors.

> Even assuming a single element feed element antenna, playing with the

I excerpted this from my latest email to my friend I'm having the
disagreement with. (Might
not even be a disagreement, it could be a miscommunication.)
Excerpt;
"The online calculator takes the (Impedance of a dipole x Ratio). This
gives you the impedance
after folding the dipole.
We still have no idea what the impedance of a dipole is when surrounded by
the reflector and
director. We do know how to change the transformation ratio once we know
what the impedance
of dipole would be in that surrounding."
Mike

Ya no doubt we all want a match.
I don't think you looked at the calculator.
I think he wants to put 50 into the data input line labeled
>Simple Dipole Feed Impedance (Ohms)<
and thinks it somehow affects the folded dipole.
I think it is just a number that is multiplied by the
calculated ratio.
Mike

The nominal impedance of a dipole in free space is approximately 72 ohms. If it is part of a system its impedance will be influenced by that system causing it to change from nominal.

Folding the dipole allows it to behave as a transformer ! Thus the nominal dipole impedance can be altered to a value that can more easily be matched to the feed line.

Commonly the impedance of a dipole that is part of a system. ie "Yagi" falls to a much lower value. Under these conditions the folded dipole can be used to raise the impedance seen at the feed point to a more usable value.

Someone mentioned "Gama match". Whilst symmetrical gamma matches can be used, single ended is popular because it is inherently unbalanced and can be easily matched to a co-axial feedline.

Hi,
Feed point impedance becomes near that when it is just a dipole(not
folded). On a haf wave element at center feed point the current and
voltage phase is such that the impedance is near that figure.

If it is vertical uater wave whip, the other half mirror image is prjected into the ground forming dipole and in that case feed point impedance at the bottom is around 50 Ohm. I am old dinosaur EE(class of 60), my brain is not as bright as it used to, LOL!

Hi,
Also folded dipole tends to have broader b/w compared to dipole.

Due to the transformer effect of folding it.

Cebic found when comparing different style programs that some behaved
well in certain circumstance where others did not. Yet all antenna
programs
are based on the use of Maxwells equations where all programs should
have the same results, after all Maxwells equations are exact and not
fudged. One of the reasons is that since Maxwells laws are exact
radiators used must be resonant at repeatable points designated as a
period.
Fact is that most users use fractional wavelength designs, usually
a half wavelength, that is not resonant at repeatable points where
the area around the datum line of a sine wave is never equal when
generated around a tank circuit.
The reason for this is "voltage over shoot" which gets smaller
with every cycle but never disappears. Thus when programs are used
based on fractional wavelength radiators the results will never show
100% accountability and in fact efficiencies derived will be in the
order of 92%!
If the radiator is of a wavelength then one is not using a "fudge"
figure
in the calculations and then becomes possible to attain total
accountability with efficiency of 100%. regardles of what type program
is used.
If one is to use exact equations, as are Maxwell equations, then
one must also use measurements that are also exact and repeatable and
that is definitely not fractional wavelengths!
What one gains from this aproach is that any radiator of any shape,
size or elevation can provide figures in the order of 100% as long as
the radiator is a multiple of a wavelength where it is resonant at
exact and repeatable measurements.
If anybody can give pointers that refute the accuracy of the above I
would be very interested in hearing them

> would be very interested in hearing them

the key is that while all the programs are based on maxwell's
equations, it is impossible to implement maxwell's equations with 100%
accuracy on a digital computer. this is true of any and all
simulation and modeling programs for electrical or mechanical design.
all such programs make approximations and take shortcuts to reduce
calculation time while maintaining some minimum level of accuracy and
precision. it is important to understand the assumptions and
simplifications that have been made in order to make proper use of the
programs. typical traps in antenna simulations are that they don't
like very small or very large length/diameter ratios... so using them
for extrement long or short wires or very fat or very thin wires may

produce results that aren't realistic. many of them also don't like very small spacing between wires, this is where most optimizer programs fall apart, they start moving wires close together and get strange results like super gain or unrealizable narrow beam patterns, often accompanied by a very low feedpoint impedance.

most reputable programs like NEC have been validated very diligently over many years and their accuracy is well documented... as are the restrictions and assumptions that apply, but you have to read ALL the documentation, not just the quick start guide. Other programs like mininec, ao, yo, yagimax, and others make even more simplifications and therefore added restrictions so they can run on a desktop relatively quickly. unfortunately they don't always document the limitations as well as the professional level products. after all the professionals have millions of dollars riding on the accuracy of designs, hams have only pennies, so it just doesn't pay to write lots of documentation or do lots of testing that won't be read for ham users.

so, while all the programs must be based on the same equations, the results they generate, especially in the fringe cases, may be vastly different. remember two maxims... 'garbage in - garbage out', and 'you get what you pay for'.

that is either poorly written satire, or a result of todays education
system... either way its 99.9% wrong... he did get the first 5 words
correct, and that English was not Einsteins native language. His
citing of Gauss's law in one of the patent claims is rather unique, as
is the inclusion of the weak force in the other... obviously a result
of too many google snippets and not enough in depth study.

"Figures in the order or 100%" of what?

All radiators of all sizes and shapes will radiate on the order of 100% of all the r-f energy that can be coupled into them through their input terminals, whether or not those conductor sizes/shapes are naturally resonant at the applied frequency.

But the fact remains that natural resonance does not occur in electrically small radiators -- while their radiation resistance is very small, and their feedpoint is very reactive. These realities make it very difficult to supply r-f power to such a radiator without relatively high losses.

As a consequence, the efficiency of the transmitter SYSTEM (transmitter + radiator + matching network, + r-f ground loss in the case of monopoles) can be very low.

To illustrate, the link below leads to a calculation of the performance of a 3-meter monopole system on 1500 kHz. Due to the low radiation resistance and system losses, and even though the short monopole itself is nearly 100% efficient at radiating the power across its feedpoint, that radiator receives only about 0.37% of the power available from the transmitter. So the system efficiency is very poor.

Such an electrically short radiator (no matter what its shape) is not very useful compared to a naturally resonant 1/4-wave monopole or 1/2-wave dipole -- both of which can radiate nearly 100% of the available power.

The calculations in the link below were made using standard equations, in a spreadsheet format to make it easy to follow and confirm. Properly constructed/used NEC models will verify the spreadsheet calculation, and the statements about the dipoles mentioned above.

There is no cause to distrust NEC when it is properly understood and properly used.

For total accuracy you MUST take account of voltage overshoot which is
neglected, so that
something other than a "period:" of a cycle will provide repeatability
of the half wave intersection with respect to resistance.
Note, "infinitesimally" is not "finite", Maxwell's equation are of
finite metrics and not close enough as in horse shoes!

Exactly.
If one uses a "period" of a cycle or a full wave instead of fractional
wavelengths
Maxwell's equations can be used in antenna programs to achieve 100%
accountability
or efficiency Where as the fudge figure of fractional wavelengths can
only achieve efficiencies in the lower 90s unless voltage over shoot
is accounted for.
Programs with optimizers recognize over shoot by providing radiators
that are all multiples of a wavelength and resonant so that the array
is also resonant as a whole.

The use of the term "nearly" does not imply total accuracy.
To use Maxwell's equations for accuracy one cannot introduce metrics
that are not absolute.
1/4 or 1/2 wave radiators cannot supplant the "period" of a wave form
and thus introduce inaccuracies. The use of different algarithums in
programing accentuate or minimise the effect of these inaccuracies
thus providing different results. Same goes for close spaced wires

where the use of "near" accurate capacitances by avoidance of all
other proximety effects again take away from the accuracy of Maxwell's
equations. An accurate measurement of resonance of a mesh as I have
shown on my web page need not be dissed because of the presence of a
computer program.

This is only true if one demands total adherence to the teachings of
the books.
Many are just theories that have been expanded upon via the use of
constants to account for the unknown and often most collapse over time
due to misinterpretation by humans.
In the case of making the static situation into a dynamic system the
mathematics are the duplication of Maxwell's laws for radiation. This
is why the use of full wave radiators satisfy equilibrium laws such
that 100% efficiencies are obtained that satisfy the teachings of
other sciences that particles and not waves are the carriers of
radiation.

Yes, and I was watching the talking heads this morning when the
Prudential commercial came on with the *_corrected_* SOS audio.

I started laughing when I saw/heard the correction and said to my wife
"I wonder if anyone else notices the error, and now the correction?"

I did a google search which led me here. LOL

The term "soot" defines the presence of particles that still contain
energy when dispelled from a chemical exchange process. In the case of
escape from the Sun's internal processes it must be recognized that
ejected particles still contain energy in nuclear form as well as
vector forces applied by the boundary equilibrium breaking form of a
leverage action.
The mechanics of what happens within the Sun's boundary is not as
important as the recognition of the equilibrium breaking vectors when
reviewing what I see as the initial carrier of radiation in the form
of an "accelerated charge". True, my spelling is not in accordance
with the rules of the english language but languages used other than
english
cannot be automatically dismissed as drivel unless correctly
translated as such.

One creates a mesh using wires. The openings in the
mesh must be small compared to a wavelength. Here's
how I modeled my pickup - don't know how accurate
it might be.

I received an email from a ham saying that he had
contacted Prudential and they had promised to correct
the Morse code S O S sounds. Is the following true?

SOS is usually sent as a prosign, i.e. a single dit
between tones?

Correct Cecil, note that you are refering to a wavelength and not a
fractional WL
This is the foundation of a Faraday cage which is the very essence of
a passive radiator. In a mesh the current applied is straight but
broken up into segments
so that the displacement current is also broken up by encircling the
holes. The holes consist of a capacitor or a field that when
intersected by the initial current field produces acceleration to
applied particles while within the confines of the intersection. This
mechanism provides the maximum acceleration possible within the
Universe per Einstein where the particle achieves the same properties
as that exhibited by light and other non visible phenomina such as x
rays etc

I have never heard that is was sent as a prosign, but IMHO it would sound
weird.

Note that your use of the phrase "in the order of" does not
imply total accuracy, either -- even for radiators meeting
your criteria.

>To use Maxwell's equations for accuracy one cannot introduce
>metrics that are not absolute. 1/4 or 1/2 wave radiators cannot
>supplant the "period" of a wave form and thus introduce
>inaccuracies.

Apparently you believe that only full-wave radiators are
"perfect" (exactly 100% efficient).

However a full-wave, center-fed dipole has a radiation resistance of
about 2,000 ohms, and a feedpoint reactance exceeding 1,000 ohms
(capacitive). That impedance would present a very high VSWR to a
normal transmitter unless some kind of matching network was used.

Even if there was no matching or transmission line loss (or r-f ground
loss in the case of a monopole), that full-wave radiator still would
not be 100% efficient because of the ohmic losses encountered by the r-
f current flowing along the radiating structure (NOT the radiation
resistance).

i don't demand adherence to the books, but since the books i learned from haven't been proven false in the last 30 years i am inclined to keep believing them. particles or waves depend on your preference, however when computing from currents in conductors it is easiest to use waves, when working at higher energies and when studying electron or nuclear interactions it is often easier to use particles. i don't see how using full waves helps since 1/2 wave antennas are self resonant, and there is no equilibrium in radiating systems... maybe if you consider perfectly conducting and lossless closed systems like waveguides or coax stubs, but once you add a radiating element energy must flow out of the system so there can't be equilibrium.

what exactly is 'voltage overshoot' and why does it affect modeling
programs? you can model an antenna without ever calculating a
voltage. all that is needed is current, which is usually much easier
to track. all voltages can be calculated from the current after the

fact if needed for figuring insulation requirements.

1/2 waves are not resonant at a constant and repeatable length. The
existance of particles has been proven in other sciences. It is just
in Classical physics where the presence of particle has not been
proved which leaves those that are stubborn to take the approach that
waves can change into particles and vica versa. As for equilibrium,
according to Hawkings it only in existence just PRIOR to the loss of
equilibrium seen as the BIG BANG. It has been billions of years since
that happened such that all surfaces on Earth that are diamagnetic are
covered by particles at rest.(Without assimilation to other mass)
With this condition in existence particles come to a screeching halt
at the magnetic field generated in arbitrary form around the earth
where added extra particles that arrive combine linearly into magnetic
lines. If a particle is accelerated outside our boundary a particle
can enter the equivalent pseudo Faraday shield via the length of
opening between the magnetic lines that allows entrance of a particle
in equilibrium. It is the attraction of such particles between the
Earth's surface and its magnetic field that creates the weather where
updrafts lifts moisture which is diamagnetic upon which the particles
reside until an imbalance occurs with change in temperature such that
particles have nowhere to go except back to Earth when the outer
magnetic field rises to saturation. Remember, the term "waves" is an
adjective whereas a "particle" is a noun and thus has substance or
contains matter. Thus it is ridiculous with respect to physics where
one disappline explains the particle as the carrier of communication
is countered by those who "know" where that the only explanation that
can be provided for the disparity is that they are both one and the
same vis interchangability!
such as particles

waves are nouns in my books. and a 1/2 wave dipole is perfectly repeatable when i measure it. maybe you need a new library, or a new bar, i want some of whatever you are drinking.

When a energy switching action occurs as with energy exchange between an inductance
and a capacitance a transient spur of voltage is created beyond the point of balance or equilibrium of the circuit. Tho this is only momentary, it delays the return of energy back to the capacitance to a lesser time. The capacitor then returns the energy back to the inductance but with a lesser voltage which again creates a transient spike of a now lesser value than before, such that the amplitude of a balanced "loss less" circuit is lost to one that defines vibration which in the human ear also creates communication. (When delving into the mathematical laws of vibration where the amplitude change and the similarity to vibration can be readily be seen.
Any way, it can be seen that with the amplitude of vibration is ever changing, so must the point where the amplitude is repeatable ie resonant, must also change. Yes, you can model anything without ever considering voltage when you choose to omit the presence of overshoot for easability over accuracy.

No, that is a cop out! A half wave length is ever changing. Because
you cannot measure the differences in the lengths does not mean that
you have consistency. You are confusing
infinity with absolute which one tends to regard as the same, to
justify the use of a mathematical step by mathematicians which defies
the position of equilibrium.
The same goes for a yagi where every element re radiates such there is
never enough elements to account for total radiation in beam form.

Back in 1949-1950 when I got my first ticket as W8EZE and became the trustee for the Walnut Hills High School amateur radio club in Cincinnati, the club had one of those World War Two devices to be used in lifeboats, with a crank on top, which you held between your legs while turning the crank. It had an antenna terminal to which we attached a dummy load. It had no other controls or terminals, just the crank and an antenna terminal. I think it only put out a few watts. Listening on 500 kc/s (as we called them, in those days) on I think a BC348 receiver, while turning the crank one heard

. . . _ _ _ . . . (long space) . . . _ _ _ . . . (long space), and on and on, as if you were sending one character with nine components, over and over again. You could write it as

___
SOS

the same way one can write

__
BT

for a double dash, or

__
DN

for a fraction bar (forward slash).

David, ex-W8EZE, who can still picture and and remember hearing the thing -- it was orange

http://www.radioamateur.it/public/mercato/index.php Mercatino dell'usato per radioamatori interamente realizzato da iz4hyz (Ezio Tulli) vuole essere un servizio per permettere l'incontro di tutti quegli appassionati di radio (RADIOAMATORI E NON) che vogliono scambiare materiale radiantistico. Qui puoi vendere, comprare o scambiare: ricetrasmettitori, antenne direttive, verticali, dipoli filari, amplificatori lineari, accordatori d'antenne, alimentatori, componenti elettronici, computer, apparati su 27 Mhz, cavo rg 58, rg8, rg213, metaldetector, valvole, radio a valvole, circuiti stampati, saldatori, notebook o altro materiale elettronico che non utilizzi più.

Until antenna programs all of which are based om Maxwell's equations
provide accountability of all forces involved to provide the 100%
efficiency, as shown by the use of
full wave radiators I have no other choice. It is as the catholic
religeon teachings when it says "give me the child and I will give you
the man." Its equivalent in education is to believe
only what the professor tells you that is written in his books as it
is he who determines
who graduates or not. Many of the masters did not have a formal
education such as Greene who had to justify from first principles
himself to determine what was correct and what was not. After serving
most of your years in life by adhering to the books it make no sense
in changing from a follower to a reseacher when the past has satisfied
your need.
As with religeon faith will always overide the tenents of science,
more so as you get older.

yeah, whatever you have been smoking is spiked with something. LC
resonant circuits do not have 'spikes', they have nice sinusoidal
energy transfer... maybe you envision the electrons sloshsing back and
forth like that swill in your glass? sorry, it just don't work that
way. enjoy your own little world, it just got one person smaller.

How about giving some pointers as to where you got this BS. Sounds
like you just made a bunch of stuff up.

Jimmie

David, your cop out is very understandable in any debate. One who has
trust in himself is willing to agree that both sides can disagree
until more information is achieved so that discussion or debate can
proceed. On the other hand those that are programed to rely on the
teachings of others as with a priest develops anger towards those
who apparently is treating his faith with disdain, by showing anger
towards those whose debate has not come to an end which does occurs
with those who deal only on faith. So yes it is not unusual for debate
to end with barbs thrown at the other debater. In your case you
entered the debate with acceptance that only a program that dealt with

full wave radiators can achieve 100% accountability of all forces.This change in direction from faith has led you into the position of providing proof that a half wave radiator can achieve 100% efficiency ONLY by finding a way where overshoot is included , indeed a heavy task that extends beyond faith.
Cheers

No Jim. Ideas with what is presented to me in science, where such can
be obtained from first principles and with agreement with known LAWS

of science rather than various theories. In this case the aproach of Gauss provided a mathematical connection to Maxwells equations which by the use of antenna programs based on Maxwell only provide accountability of all forces. This is easily proven when use of a program that is optimized to account for all forces involved in radiation such that the solution provided is termed 100% efficient as opposed to planar or other designs that cannot achieve 100% efficiency because of the non accountability of the recognition of "over shoot". One always looks for 100% accountability of all forces such that 100% efficiency is achieved.

If you are in the early stages of education it would be folly to bring forth suggestions to the contrary of those presented in the books and your professor since these are the standards against which determines whether you graduate or not. Obviously this is not the time to debate differences. As life proceedes one becomes comfortable with alignment with ideas and teachings that conform with those around you because in general your wages depend on it. Thus you are dealing with faith regardless of the attainment via first principles that produce conflict.

So yes, your only response to continue a science debate is to provide counter proof from first principles that is available some where in a book! Compared to that task it is so much more convenient to exit the debate on a statement that does not require a proof. Thus anger comes to the fore and debate or a thread comes to an end.

Cheers

Well David prove it based on science instead of expecting me to accept
you on faith.
That is only accomplished by the source providing replacement such
that consistent amplitude is maintained. Without this replacement the
amplitude will show degradement as seen with vibration or a simple
pendulum clock that exhibits the two vectors previously mentioned ie
one linear and one circircular. There is no free lunch as with
perpetual motion
when equilibrium is broken.
Cheers

Art, you are the Master here at asking the readers of your posts to accept them on faith, while having provided no scientific proof for your posts whatsoever -- and while denying or at least ignoring the validity of other posts containing provable scientific and experiential evidence to the contrary.

Why should any well-educated person accept _your_ faith-based, and unproven beliefs?

True. When circumstances dictate that I pay attention and I'm in a
good mood, most programs behave normally. However, when circumstances
are not so favorable, such as last week when I replaced my septic
tank, all of the software I was using literally stunk.

>Fact is that most users use fractional wavelength designs, usually
>a half wavelength, that is not resonant at repeatable points where
>the area around the datum line of a sine wave is never equal when
>generated around a tank circuit.

Last time I checked, the definition of a half wave automagically
includes any external or magical factors that might change its length.
For example, if you submerge the antenna under water, the increased
dielectric constant will cause the half wave length to somewhat
shorten. While the previous length has changed, the new shorter
length is still a half wavelength.

>The reason for this is "voltage over shoot" which gets smaller
>with every cycle but never disappears.

Overshoot can easily be fixed with a Cutts Compensator.
<http://en.wikipedia.org/wiki/Cutts_compensator>
Every time you cycle your antenna, the recoil tends to make the barrel
climb a bit. This is the cause of the overshoot. A suitable Cutts
Compensator attached opposite the feed point should help prevent
overshooting the target.

>Thus when programs are used
>based on fractional wavelength radiators the results will never show
>100% accountability and in fact efficiencies derived will be in the
>order of 92%!

95.718% of all statistics are wrong. If you're using single digit
accuracy and single digit significant figures, 92% rounded off is
equal to 100%.

>If the radiator is of a wavelength then one is not using a "fudge"
>figure
>in the calculations and then becomes possible to attain total
>accountability with efficiency of 100%. regardles of what type program
>is used.

Half wave wire dipoles do tend to be resonant somewhat shorter than the free space wavelength. That's due to sales and value added tax placed on antennas by the government. You'll always come out a bit short when dealing with them. However, the last time I checked, the cut length was only about 5% shorter than the free space half-wave length. Did the antenna tax increase to 8%?

>If one is to use exact equations, as are Maxwell equations, then
>one must also use measurements that are also exact and repeatable and
>that is definitely not fractional wavelengths!

My antennas are exact and repeatable. Not only that, I can also repeat my mistakes every time.

>What one gains from this aproach is that any radiator of any shape,
>size or elevation can provide figures in the order of 100% as long as
>the radiator is a multiple of a wavelength where it is resonant at
>exact and repeatable measurements.

Perhaps. If you buy your antennas out of state or on eBay, you can avoid paying the 5% antenna length tax. However, you are required to pay Use Tax on any out of state purchases where the vendor neglected to collect the antenna tax and forward it to the Calif Franchise Tax Bored:
<http://www.ftb.ca.gov/current/usetax.shtml>

>If anybody can give pointers that refute the accuracy of the above I
>would be very interested in hearing them

Why? You haven't proven your point, demonstrated the phenomenon, or otherwise provided anything worth tearing apart. For all I know, your antennas are shorter than expected because of magic, enchantment, sloppy construction, mis-measurement, or all the aforementioned. Anyway, the problem is easily solved. Just increase your AC power line voltage about 5% and your numbers should increase by the same amount.

Very true, but the measured length is never repeatable. Only at the
point of a period
is where it is repeatable which is how a cycle comes into being.

Ofshoot can be essentially removed or minimised by just the addition
of a resister but such methods are not included in antenna computer
programs.

Again what ever trips your trigger, horse shoes or Maxwells equations.
Only when accurate metrics are inserted in a program can the accuracy
of Maxwell's equations be shown and the half wave length can never be
stated accurately.

Maybe true but physics demands accuracy which explains the heavy
useage of constant added to justify the use of an equal sign. Same
thing goes for the myriad of particles invented that are not seen or
measurable. This because those who delve in physics sometimes replace
a constant with a new invented particle that can substantiate
equilibrium or its cousin "equal"
>
> --
> Jeff Liebermann   je...@cruzio.com
You know, a well known former ham Stephen Best got hold of a new
antenna program
that had strict adherence to Maxwells laws. The program relied on
Poynting circle as being representitive for all forces in radiation.
The program ,probably more than I can afford. produced a radiator that
was not straight according to the old wives tale that is propagated by
hams. It showed something like a tennis ball where multiple
wavelengths of radiator were stuffed inside and where balance or
equilibrium was obtained. In his study which was around a half wave
radiater produced a radiation pattern that was a perfect hemisphere
that all on this group stated was impossible to attain. (actually it
was based on a full wave where the ground plane supplied the mirror
image) Possibly in our time, that will make it into the newer physics
books, that will force the re thinking of radiation. This paper is on
the WWW but I leave it to you to show that it must be in error as it
is not yet in the books!
At the same time opponents will bring forwards Toms adage W8TI, that
for maximum efficiency a radiator must be straight, thus leaving him
with the onus of showing that Steven Best efforts were all wrong by
the use of the soon to be corrected theory corrections
before old theories are fully discounted where all may read it for
themselves in a book.

Art

You ask others to prove things based on science while you ignore proven
and demonstrable science and make up your own "facts".

You have never proven or demonstrated ANYTHING, yet have the frigging
balls to require others to do so.

A hypocrite by any other name is still a hypocrite.

I do not have to prove anything to you! The first project is to obtain
a patent that is desired by those skilled in the art of making money
on new antenna disclosures.
You have neither of those requirements. Because you are unarmed with
respect to having skill in the science of antennas it is normal to
gravitate towards insults where the record shows that your knowledge
of antennas is negligeable. It is impossible to debate science with
one that excells only with the skill of memory that parrots only that
which can be memorised by a reading of a book with zero understanding.
Ofcourse, if you had a tangible record on the teachings on the science
of antennas you surely would have provided evidence of same, rather
than the use of slander to provide perceived elevation of your station
in the presence of Madame Guillotine, where the loudest voice becomes
a leader of what is just a mob. I have never seen evidence in your
postings that you have had a tangible trail of education that would
substantiate your self perceived expertise in the field of antennas
thus you do not have a real beef to show on this thread.
As for your statement "as for all I know" it is better that you
believe in magic where faith overcomes physics.

Soot refers to carbon particles resulting from the incomplete
combustion of a hydrocarbon. ... or particulate matter, whose size is
measured in microns. You are confusing the term with sub-atomic
particles.

You are like Humpty Dumpty in 'Alice in Wonderland'.

“When I use a word,” Humpty Dumpty said in rather a scornful tone, “it
means what I choose it to mean, neither more nor less.”

And who has paid for use of your patents? And how much? I am sure we
all know the answer. No one, and nothing.

My antenna designs are actually being used very successfully, and yours aren't.

You are a fraud and a hypocrite.

So here you are again with nothing of value other than insults.
You mentioned that credible evidence has been presented(obviously not
you)
that provides credible evidence supplied that refutes my position. Why
not push that point over and over again where the credible evidence
becomes readily accepted by those skilled in the art? The church once
declared that the World is flat and those who do not follow the
teachings will be excommunicated. Eventually scientific knoweledge
increased as the Century past such that teaching became discreditedand
the church had to recant to allow the teachings of faith by the
servants of the church could continue. Come to think of it I bet the
findings of Steven Best has already made it in the latest books for
assimilation by those now entering college regardles of what the
naysayers promote by refuting change to all that every thing is now
is known about the science of antennas. These people eventually die
thus leaving the education field to review the sciences of old and
update them where necessary so they may be duplicated by plagurizers
that are natural followers.

So you are a millionare today? Patent number? The present industry is advocating the invention of a new science with respect to obtaining smaller radiators. Get in there and double your money while the consortium continue to struggle with the design of a new technology.alternative than that supplied by nature. If you had such knowledge you would not be persueing insults in place of debate.

I'm not claiming or implying (as you are) that I'm making money on anything. Just that my antennas are actually used by real people quite successfully.

And given what you've been saying to anyone that responds to you, you have no place to stand on insults since you are great at supplying multiple paragraphs of them at a time. At least mine are pertinent to the subject.

I have no interest in small antennas or making money on them. I am however interested in the truth and antennas that truly work. And you are interested in BS and self promotion.

Have fun with your fraud, hypocrisy and lies.

And try to learn to spell.

One cycle = one period = one wavelength
Do you have a problem with this?

>Ofshoot can be essentially removed or minimised by just the addition
>of a resister but such methods are not included in antenna computer
>programs.

Adding a resistor will increase the resonant length of an antenna by
5% to 8%. Amazing. I didn't know that. Since resonance is where the
inductive and cazapative reactances cancel, leaving only the real part
of the antenna impedance, I would think that adding a resistor
anywhere would have no effect on the reactive components.

>Again what ever trips your trigger, horse shoes or Maxwells equations.

When I was younger, it was sex, drugs, and rock and roll. These days
it's pills, politics, and entertainment value that keeps me going.

>Only when accurate metrics are inserted in a program can the accuracy
>of Maxwell's equations be shown and the half wave length can never be
>stated accurately.

How accurately would you like them to be stated?
1%? 0.1%? 0.00000001%
Accuracy is usually expressed with numbers. I fail to see any
numbers. There's also a question of what's "good enough". Infinite
resolution and accuracy doesn't do me much good if the operating
bandwidth of the antenna is substantial, or the operating requirements
of system are rather minimal.

>> My antennas are exact and repeatable. ï¿½Not only that, I can also
>> repeat my mistakes every time.
>
>Yes you have shown evidence of that.

To err is human. Reassurances are not required.

For my mistakes, I'll accept responsibility but not blame.

Two wrongs don't make a right, but do eliminate two possibilities,
thus eventually leading to the right answer.

Positive feedback is inherently unstable. One does not learn by
getting positive acclamation and praise. One learns from negative
feedback which is inherently stable and a much more effective learning
experience.

>Maybe true but physics demands accuracy

Physics does not demand accuracy. However, my customers might.

>which explains the heavy
>useage of constant added to justify the use of an equal sign.

None of my work is linear. Therefore constants added as fudge,
finagle, or tweak factors are useless. I prefer to multiple my
results in order to conjure the correct answer.

>Same
>thing goes for the myriad of particles invented that are not seen or

I think you mean this:
<http://www.cst.com/Content/Applications/Article/A+Small,+Efficient,+Linear-polarized+Omni
-directional+Antenna>
I've been trying to understand it for some time.

Again, it's not my place to find your errors. It's your place to
prove and demonstrate your allegations.

>At the same time opponents will bring forwards Toms adage W8TI, that
>for maximum efficiency a radiator must be straight, thus leaving him
>with the onus of showing that Steven Best efforts were all wrong by
>the use of the soon to be corrected theory corrections
>before old theories are fully discounted where all may read it for
>themselves in a book.

Dr Best didn't seem to mention anything about the design being any
more efficient than a larger antenna. He had a design requirement to
fit an antenna inside a 0.04 wavelength diameter ball, and optimized
his design around that requirement. Getting 1.6dBi of gain out such a
small antenna is impressive.

Incidentally, his design is NOT a half-hemisphere. He uses the
symmetry of the antenna to dramatically reduce his calculation time.

Yes, there are some things that NEC doesn't so very well, or rather
other programs do much better. For example, for microstrip and slot
antennas, I'm trying to learn Mstrip40:
<http://www.spl.ch/software/MultiSTRIP/Manual.htm>
when not posting inane drive to Usenet.

Ok jeff your turn wih aiming the cannon.
No ofcourse not, as long as the cycle is complete and terminates
and terminates at the point designated as the period.
Good enough ?

Enough according to my needs. If the needs are expanded then their is
no point
in expanding errors implanted for past convenience. O.K ?
> Accuracy is usually expressed with numbers. I fail to see any

Quite true. Only one who has experienced many bankrupcys
has the necessary wisdom to become rich The wisdom is usually at the
expense of others
OK?
>
> Positive feedback is inherently unstable.
Why do you think that?

 One does not learn by
> getting positive acclamation and praise. One learns from negative

I believe my answer with respect to attaining wisdom is a suitable
response for that!
>
> >Maybe true but physics demands accuracy
Exactly where space for a constant is provided as learning improves.
>
> Physics does not demand accuracy. However, my customers might.
Might is a untangible. If one wants to expand on the design of smaller
antennas one does not pursue a fudge factor which suggests that the
smallest of smallest of radiators will also meet ones needs. That is
like adding height to buildings built on sand
instead of first ataining a sound foundation in advance of any
expansion

Well an "equal" sign in mathematics designates balance on both sides
of the sign. Was it the arabs that expanded the term to equilibrium
that could accompany the use of boundary laws?

That cannot be done when others rely on theories because they are seen
written in a book. It takes corroberation with existing laws to supply
a modicom of science teachings where those agreements can then be
built upon. This is a repeat of the battles of faith versus the

observations and deductions provided by science.

Yes, but more important was the ability to stuff wavelengths of
radiator showing past erronius suggestion that a radiator must be
straight.On top of that he attained a hemisperical radiation pattern
that this group stated was impoissible. Thus another false old wives
tale was debunked, By the way the paper in no way suggested a
"electrically" small antenna, only a "physically" smaller antenna, so
you need to re read the paper.
>

I have stated same

 For example, for microstrip and slot
> antennas, I'm trying to learn Mstrip40:
> <http://www.spl.ch/software/MultiSTRIP/Manual.htm>
> when not posting inane drive to Usenet.

Then you are a better man than I Gunga Din. It was the very
interpretation of the phenomina of a slot antenna that led to
confrontation with the idea of particles as the carriers of radiation.
Perhaps you can find errors in that assertation which is so much less
difficult in convincing same to those who abide purely on faith.

Phew, that was a long questionaire but as always my life and thoughts
is an open book.
I hope the above satisfies your needs!

You simulate it as a wire grid, like a screen. Download the free EZNEC demo program, or just the manual, from http://eznec.com, and look in the index under "Wire Grid Modeling" for more information.

This technique is widely used and generally gives very good results.

Just as a non-insulting question, to what do you attribute the principles you describe not being discovered until radio and antenna technology becoming fairly mature? Given that physically small radiators have been desirable just about forever, it is interesting that no one has not accidentally stumbled upon your type of antenna at least once in the past hundred years.

One would not have to ascribe to your interesting views on physics to accidentally produce something that works according to your principles. Sweeping an antenna over a wide range should produce clues, if not understanding.

Which is to say I'd ordinarily expect things to happen in a particular order typically in one or two modes:

1. Discover the effect accidentally.

2. Reproduce the effect.

3. Come up with good theory to support the effect.

Way two

1. Theorize the effect.

2. Build the apparatus to prove it.

3. Reproduce the results.

Either way is fine much has been learned through honest sweat as well as cerebral horsepower.

I think Art is trying to get the members of this group to test or affirm his theories for him so all he has to do is sit on his butt and toss out hair brained ideas. IMO he is desperate for either money or recognition or maybe his life is so boring doing this is all he has left. That would be very sad. I guess if we wanted to be really mean to him we could all just agree with everything he says.

Most of the bandwidth enhancement on a folded dipole comes from the
fact that it's a "fatter" radiator rather than because it's folded.

Finally saw a commercial that's probably the one you're talking about.

It sounded more like "VMS" to me, but based strictly on the dots and
dashes, ignoring the timing, it was "SOS."

It could be done quite easily. All you have to do is build the
antenna, and then compare it with known benchmarks.
But of course, that would be using common sense. :/
It would also prove your theories are flawed, which is why
you won't do this in public, if at all.

> > >themselves in a book.

#1, it's W8JI, not W8TI, and what he said was correct. You are just
taking what he said out of context and are distorting it to fit your
agenda. If you have a straight radiator of a certain length, yes, the
most efficient configuration will be a straight line.
If you take this same length of wire and mangle it into various
bends, twists and turns, loss will rear it's ugly head.
Deal with it. There is no free lunch.

>

Ugh.. 1.6dbi gain is still less than a straight dipole.. There is no
free lunch when you use linear loading. Which BTW, is a technique
as old as dirt.. :/
Just because someone decides to call it a fancy name such as
"fractal", does not impart magic qualities to this old as dirt
technique.
BTW, it's quite possible one will need a matching device with such an
antenna. Even more loss. :(
If you don't require matching for this wonder of technology, I'd
suspect you probably have re-invented the dummy load.

But maybe that's a moot point, being as you have ignored others
that point out the same thing over and over again.
IE: all radiators are quite capable of radiating nearly all power
that is applied to them. It's getting the power to them without
it turning to heat which is the real trick. Good luck in the contest.
You are going to need it.

>
> Phew, that was a long questionaire but as always my life and thoughts
> is an open book.

I thought you had a problem with books? According to you, books
corrupt the mind. Does that mean we would be best off to ignore
everything you write?

> I hope the above satisfies your needs!

I doubt it was as good for him as it was for you. You just seem
to lay there. :/

Of course, the 'transformer effect' is unlikely to increase the bandwidth by itself, and when the common type of half-wave-line balun (and 4:1 impedance transformer) is used to connect the dipole to co-axial cable the resonant nature of this additional half wavelength is likely to impair the bandwidth to some extent (by introducing additional reactance at frequencies for which its length isn't a true half wavelength).

Certainly the additional fatness of the folded-dipole structure must contribute to improved bandwidth by reducing the slopes of the terminal resistance and reactance, but the treatment given in the link provided above - suggesting that the susceptance added at the drive point by the 'parasitic' parallel wire or rod, joined to the driven element at its ends, has insignificant effect - is a rather broad generalisation which may not be true for some geometries (i.e. length/thickness ratios of the wires/rods and their spacing). Generally, it's dangerous to generalise!

There's quite a lot going on in a folded dipole. Some further insight (on allied, but not the same, topic) is offered in http://www.physics.princeton.edu/~mcdonald/examples/cutantenna.pdf.

Source record: 12003

Off topic though this certainly is, I'm posting this because I know that several people who frequently post in rraa have one or more patents, and there have over the years been a number of comments here about the sorry state these days of patents and the patenting process in the USA. Moreover, with some notable exceptions, postings in this newsgroup often show intelligence and thoughtfulness on the part of the people making the postings, more often than in many of the other newsgroups I read.

With that said, I'd enjoy reading comments on the NY Times article "Inventing a Better Patent System", which you can see at <http://www.nytimes.com/2009/11/17/opinion/17pozen.html?hp>. The author makes five specific recommendations for amendments to patent law which he believes would improve the situation. I'm a (retired) pure mathematician with no patents whatsoever, and my knowledge of law is nil. But what he says seems to make sense to me.

If you can illustrate why you agree, or disagree, with points made in the article by referring to antenna patents (or other patents on related matters) with which you are familiar, that would be good, and it would make the issue a little less off-topic. Thanks in advance for reading the article and making your comments.

Hi David,

I have patents, and yes the system is broken - but not in the ways
this author describes (but, oddly, is separate from his fixes).

The author comes up with some rather odd objections which are like
moving deck chairs on the Titanic. Some of it is quite naive:
"Yes, it makes renting movies a snap,
but was it really a breakthrough
deserving patent protection?"

The patent examiner is specifically prohibited from denials based on
hindsight. The patent must disclose prior art, and if that art
anticipates the use (as something within the art of the practioner)
then there is a basis of denial, but the examiner cannot make that
leap without this paper trail. One legal tenet a patent lawyer told
me last week was that "Only God can create, man assembles all
invention from other existing ideas."

The following quote is an outright wet-dream:
"One root of the problem is that patent examiners,
many of whom are young or lack practical
experience, are not qualified to evaluate
whether complex claims in biotech or
physics meet the most critical tests."
This is patently absurd from an historical basis. Examiners have
always been young and lacking experience - the office is the first
rung in a ladder of their career as patent lawyers. How any NYT
scribbler would expect the economic model to suddenly invert
(practiced lawyers becoming examiners for far less pay) is misty eyed
in the extreme.

This also brings us to the second glaring error in that quote which I
repeat in part here:
" to evaluate
whether complex claims in biotech or
physics meet the most critical tests."
This speaks to the validation of science which is NOT part of the
examiner's job. This is confusing the specification (the description

written in what should be clear English) with the claim (the list of relationships and associations). Examiners deny a patent on the basis of the claims made which do not rely on "this proves Einstein was wrong and I have invented of something that Gauss forgot."

There are very few criteria to be met: is it novel? Is it marketable? Neither of which demand scientific proof. Someone might demand that novel requires proof, but this is on the basis of claims alone. Does your invention's claims appear somewhere else? The examiner is paid to wade through the 6 million patents to ascertain that.

Now, let's move on to those suggestions.
"To help fix this, Congress should pass an
amendment allowing experts in the field to
submit explanatory or critical comments on
patent applications."
This doesn't go to the matter of claims of prior art. I've spent enough ink on that.

Next:
"Next, Congress should require that all
applications be made public 18 months
after they are filed."
I would argue 18 months is arbitrary (who is this scribbler working for?). Why not next week? The proposed solution is to combat what is called Submarine Patents. Basically, this was responded to in 1995. I had a patent that was underwater for 4 years. This wasn't out of some business ploy, but simply because the brief was so huge (several hundred pages) that it fell behind one of the filing cabinets and was lost for years.

Next:
"Congress should eliminate the 'could have raised clause.'"
Reasonable.

Next:
"Fourth, Congress should provide limited
new immunity to all inventors who choose
to protect their innovations as trade secrets
rather than patents."
Trade secrets are a risk that should be borne by the one who wishes to protect their IP through their own devices. This goes into estoppel and laches - law that has a long history. If you cannot keep your cat in the bag - so be it. Whatever is being spoken to here in this author's suggestion does not have to be cloaked in the mantle of Patent reform.

Last:
"Congress should adopt a first to file rule
for awarding patents between competing parties.
America is the only major country that tries to
ascertain who was the first applicant to invent the

product or procedure."
The second sentence is not true, but when did facts ever matter? Indeed, the first to invent versus the first to file has been contentious since Alexander Graham Bell and the telephone (and many others through the decades). Invention is a populist notion in a populist nation. Europeans see things as law, not popularity. This, too, was a topic that has been answered in 1995 and is now being crow barred to fit globally. We have learned to cope with it over the centuries and Europe doesn't have a dog in this fight, unless a foreigner needs coverage here.

Going beyond as there are some interesting things about Patent law to add to this. You can be sued for practicing your patent! This usually stuns non-lawyers so an illustration needs to be illustrated:

The LED is patented. As far as the patent examiner can tell, nothing within the patent identifies any anticipated product outside of its claims (the inventors didn't elaborate beyond the general notion that light could be emitted from a semiconductor).

You invent the Red LED. The patent examiner reviews prior art, and sure enough the LED inventors never anticipated a single wavelength application. BINGO! Your patent is issued.

You go out, build a plant, produce a bajillion Red LEDs and are immediately served a cease and desist order for infringement! The LED patent blocks your patent. The only thing you have gained is a way to keep the original LED patent holders (and everyone else too) from making Red LEDs - if it matters to them.

There's a bajillion other oddities, but time has come to close here.

Dear Group: Richard has done a good job on the Times article.

I echo that the use of a first-to-invent system fits our Republic's ideals.
The efforts involved in "interferences" where determinations are made as to
who is first are a very minor part of the process.

Left off entirely is the issue of the bonus system used in the PTO that
appears to reward not issuing patents. Issued patents have gone from about
65% of applicants to about 40%, and much more telling is a reported six fold
increase in the number of applications waiting for judgment in the appeal
process. I now tell potential patent applicants that they must expect to
use the appeal process as that may be the only way their application is
evaluated by judges who are not influenced by the bonus system.
Applications take too many years and have become very expensive. Once the
US patent system was the least expensive and was fast.

It is unreasonable to expect things like the Times to understand anything
that is a bit complicated.

See:
<http://802.11junk.com/jeffl/antennas/mfj1800/>
The annotated NEC2 file is attached to the "Main" JPG. Cut-n-paste
should get you something to play with.

This is NOT an exact representation of the MFJ1800 antenna. The
elements are round, not flat. The driven element is a squared off
approximation. Some of the dimensions are questionable. Note that
the feed impedance is normalized to 288 ohms, the characteristic
impedance of a folded dipole, not 50 ohms.

>Here is a drawing and some more pics.
>http://i395.photobucket.com/albums/pp37/Qmavam/MFJPaintFileJPG.jpg

I need an overall length, measured from the CENTER of the driven
element (the plastic screw hole) to the CENTER of the last director.
That's because a tiny error in the spacing between elements at 1.060"
(2.69cm) grows rather rapidly when multiplied by 14 elements.

NEC works in wavelengths or meters, not inches. Think metric and
forget about using inches.

Please check the length of the first and 2nd directors. I don't
believe MFJ would make them the same length as the other directors.

Also, measure the coax balun cable dimensions. Mostly, I'm interested
in the:
1. Shield to shield length.
2. Center pin to start of folded dipole length. (i.e. exposed center
wire length).
3. OD of center conductor wire.
4. ID of shield.
5. A good guess as to the type of dielectric (foam, solid, or PTFE).
6. Any markings that might identify the coax.

I'll do a better job of modeling the folded dipole driven element
later. Modeling all the asymmetrical elements is going to require
more time than I want to spend. Maybe if I get inspired to RTFM. It
seems easy, but looks tedious.

What I've deduced from the model so far is:
1. The characteristic impedance is over 300 ohm without the coax balun/matching/whatever section.
2. A 1/4 wave coaxial matching section isn't going to work as the highest commonly available impedance coax of 93 ohms will only match 50 ohms to about 173 ohms. That thing doesn't look anything like a 4:1 balun (unless there's something we missed under all that shrink tube).
3. With a suitable 4:1 balun, the antenna is slightly shy of the advertised gain spec of 15dBi:
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1800>
with a gain of 14.3dBi. Close enough.

A few changes. I changed the simulated folded dipole into something
more closely resembling the original MFJ folded dipole. I also
changed the characteristic impedance to 200 ohms so that more closely
resembles a 4:1 match to 50 ohms. Of course, the VSWR went from
tolerable to horrible (10:1). I suspect I did something wrong in
locating the feed point, but I'll fix that later. When using a
geometry editor/generator, I turned my nice neat NEC macros into
unreadable gibberish. Sigh... I'll also fix that later.

Gain is still 14.1dBi.

My model uses 1/4" elements, and for just the loop, Z = 150 Ohms @
2250 MHz

For the Reflector, driven loop, and director, the Z = 72 Ohms @ 2450
MHz

The loop ends are 8 segments(22.5 degrees). EZNEC complains of
len/dia ratio being too small, but there's nothing to be done about
that. 20 wires total, 62 segments total (for just the first three
elements).

>NEC works in wavelengths or meters, not inches. Think metric and
>forget about using inches.

I went with the dimensions provided - inches no problem.

>6. Any markings that might identify the coax.

THIS is where error is going to intrude, big time. I think there's too much attention to this detail for what it is supposed to do - but I have already written on that subject.

To answer the original question, the folded loop Z drops due to the proximity of the other parasitic elements (a normal consequence). However, as to calling it a folded loop seems to be straying from conventional usage as those loops are rather sweeping (large). This may be deliberate if my data conforms to the usage found.

As a side note on just three elements, there is a degree of up/down/side look due to the loss of co-planar symmetry of the loop with the other elements. Adding more directors would probably hide this.

More changes(tm). I fixed the feed point on the flattened folded
dipole and the VSWR magically came down to normal (1.47:1 into 200
ohms). Vertical gain dropped to 13.1dBi, but horizontal gain dropped
to 6.35dBi. Something (else) is wrong.

I'll fix the macros so that the NEC2 file is readable, later.

The original has an asymmetrical cross section of .330cm x 0.200cm
(from the supplied dimensions). I decided that a suitable equivalent
would be a round rod, with the same circumferance. of 1.06cm. That's
a 0.338cm dia rod. However, I don't know if this is a realistic
approximation. Your 0.635cm diameter rods might be a bit wide.

My folded dipole ended up with 4 segements (45 deg/seg) at each end
and about 42 segments total. 4NEC2 also initially complained about
the ratio of the segment length to rod diameter, but I reduced the
number of segments and reduced the wire diameter to correspond to the
copper tape thickness. 4NEC2 was then happy.

I kinda like to do things in wavelengths because invariably I end up
recycling (plagerizing) my own designs to operate on different
frequencies. With wavelengths, that can be done by just tweaking one
or two numbers (GS scale structure card). However, this abomination
of an antenna design is unlikely to be useful at other frequencies, so
I used meters and not worry about scaling. I find that I make many
more errors when using inches than with metric.

>>Please check the length of the first and 2nd directors. I don't

>
>This is imparting too much engineering for their product.

I'll be generous and not pass judgement on this contrivance until I understand this antenna with its rather odd balun, or whatever it is. It's possible to build an equal space director Yagi-Uda antenna but not with equal length directors. If I feel ambitious, I might feed it to an optimizer and see what optimizing the first two director lengths can offer.

>I have already written on that subject.

Me too. However, I was rather guarded in my criticism since I didn't really understand the design of the balun and the purpose of the ferrite beads. My best guess was a 1/4 wave (or 3/4 wave) coax matching contrivance made from RG-62/u (93ohm) to match to 173 ohms. If the feed impedance came anywhere near 173 ohms, and the coax turns out to be 93 ohms, then it has a chance. However, even if it met all the criteria for an effective 1/4 wave match, the sloppy construction and exposed center conductors will certainly have detrimental effects.

>To answer the original question, the folded loop Z drops due to the

Well, the impedance is going to be somewhere between a circular full wave loop (about 100 ohms) and that of a folded dipole (about 288 ohms). The problem is that this folded dipole isn't folded very much and more closely resembles a loop. In addition, the reflector and 1st director are not particularly close to the driven element. That makes me suspect (i.e. guess) that their effect on reducing the feed impedance is going to be minimal.

J. Mc Laughlin wrote:
> Dear Group: Richard has done a good job on the Times article.

I agree. I also think that of all the articles I've seen this one was the best. While it was very limited in its understanding of the problems, at least it was an attempt to fix the problem instead of scrapping the whole system or reducing its scope (e.g. eliminating software patents).

> I echo that the use of a first-to-invent system fits our Republic's ideals.
> The efforts involved in "interferences" where determinations are made as to
> who is first are a very minor part of the process.

First to invent has its problems too. Without a system of publication, one can simply describe inventions in dated documentation and wait for other people to patent them. Then you just show up with proof of first invention and collect your patent someone else paid for.

Possibly a system where patent applications are published within 30 days of recepit and the amount of time to file claims of prior invention are limited to a year or 18 months.

This would also require the publication of provisional patent applications which is currently never done.

> Left off entirely is the issue of the bonus system used in the PTO that

> Applications take too many years and have become very expensive.

The effect of the bonus system has been to change a patent application from the final step in the process to one near the begining. This has been a windfall for the top patent lawyers who can successfully navigate the appeal process and a disaster for the small inventor or patent agent.

>Once the
> US patent system was the least expensive and was fast.

I expect that one of the smaller countries with a minimally functioning patent system will take over. They will, for a large fee, issue a patent quickly and quietly. Something like for a $100k fee, they will issue a patent without publication of the application, in 6-8 weeks.

Once they issue the patent, as US patent via the Patent Cooperation Treaty is assured. It does not matter if the US application takes years or there are any appeals and so on. You have what is in effect a US patent and just have to wait for the paperwork to catch up.

> It is unreasonable to expect things like the Times to understand anything
> that is a bit complicated.

Compared to their usual technology articles, which are just re-aranging the paragraphs in press-releases, this one was wonderful.

Geoff.

My guess is solid poyethylene, if you have a test other than poking it
with a pin to get feel of it, which I did.

No help there.

> That thing doesn't look anything like a
> 4:1 balun (unless there's something we missed under all that shrink tube).

Looks like 4 toroids that slide over the coax, you can see the outline of
the edges of each toroid.

By this statement, do you mean the spacing between elements is large
so it looses it's folded loop characteristics?

Mike

Hi Mike,

I was a bit obscure on that last point. YOUR antenna's looped dipole has rather large turns for a folded loop. A folded quarterwave (for verticals) or folded halfwaves (for dipoles) generally show 4X impedance boost for same sized wire/element in the loop. Some designs use different sized halves of the loop to change the multiplication factor as this is the primary determinant with closely spaced folds.

However, your antenna has rather larger spacing which may lower the multiplication factor IF my model conforms to actual. This choice of larger looping may show MFJ's engineering talent in achieving a natural match. I don't think the rest of the array is going to matter much in getting the "most" gain it could, but it is probably good.

Hi Geoffrey,

I think they should be sent to the bit-bucket. This is a point where
claims are specific and a huge amount of published patents have
clearly been built from work existing in the Public Domain for
decades.

Going back to the populist nature of an "Inventor," too many are
corporations hiding behind this cultural perception while they crush
innovation with offices full of attorneys hammering down individuals
who can't afford the cost of litigation.

>First to invent has its problems too. Without a system of publication, one
>can simply describe inventions in dated documentation and wait for other
>people to patent them. Then you just show up with proof of first invention
>and collect your patent someone else paid for.

It doesn't work that way. What you are describing is an IP that has
been ceded to the Public Domain, not patented as if it were a grab at
the brass ring.

>Possibly a system where patent applications are published within 30 days of
>recepit and the amount of time to file claims of prior invention are limited
>to a year or 18 months.

Prior art is not a limited, moving window in time. Otherwise, we
would be flooded with re-inventions of the telephone every year and
half by your method.

>This would also require the publication of provisional patent applications
>which is currently never done.

They are always done. For the bulk of invention, provisional patents
are often copies of press releases, journal articles, degree work,
papers for presentation and so on. And it hardly matters unless the
party files an actual application. Again, this was put to bed in 1995
and is supported by the international field. In fact, you need only
attach one claim to a provisional patent and you have international
protection. The claim can even be changed later!

>The effect of the bonus system has been to change a patent application from
>the final step in the process to one near the begining. This has been a
>windfall for the top patent lawyers who can successfully navigate the appeal
>process and a disaster for the small inventor or patent agent.

Sound like the Patent system I was very much a part of in the 80s and
90s. Being a small inventor, it was actually quite to my advantage
(the market practicalities aside).

>I expect that one of the smaller countries with a minimally functioning
>patent system will take over. They will, for a large fee, issue a patent
>quickly and quietly. Something like for a $100k fee, they will issue a
>patent without publication of the application, in 6-8 weeks.
>
>Once they issue the patent, as US patent via the Patent Cooperation Treaty
>is assured. It does not matter if the US application takes years or there
>are any appeals and so on. You have what is in effect a US patent and just
>have to wait for the paperwork to catch up.

I would think that 14 years of experience would have revealed this
anticipated grief by now. Getting a patent faster does not make the
ideas come sooner to submit that fast-track application.

Amazing...

>> Also, measure the coax balun cable dimensions. Mostly, I'm interested
>> in the:

Nice. I'll see if I guess(tm) the coax type. It doesn't seem like a
good fit for any of the common cables as the center conductor is
somewhat larger diameter than any of these listed. See if you can
find an exposed center conductor without any tinning or soldering.
<http://www.epanorama.net/documents/wiring/coaxcable.html>
One more dimension... the approximate outer jacket diameter of the
coax (not including the shrink tube).

>My guess is solid poyethylene, if you have a test other than poking it
>with a pin to get feel of it, which I did.

Weird(tm). Low loss coax would need to be foam or teflon. Solid
polyethylene is easier to work with, cheaper, but not the best.
However, a short piece like this balun would not have much loss, so I
guess it doesn't matter what flavor is used:
<http://en.wikipedia.org/wiki/Coaxial_cable>

Gotta do paying work today. I'll play with this more in the next day
or two (so I don't forget what I'm doing).

Thanks. 50 ohm coax does not make it a matching section to a 200 ohm
folded dipole. However, the ferrite beads are a good way to simply
block the reflected power from the folded dipole so that it looks like
it's matched. In any case, that reflected power is lost (converted to
heat) in the ferrite beads. So much for efficiency. When I change
the characteristic impedance of the model from 200 ohms to 50 ohms,
the VSWR climbs to 5.5:1. Yech. (Note that the radiation efficiency
is 75% with or without the mismatch).

I suppose the antenna could be made to function by replacing the coax
section with a real 1/4 wave 4:1 balun, but I'll leave that to MFJ to
figure out.

If you need some more entertainment value, it would be interesting to
actually measure the gain of the antenna. Find a known good reputable
antenna with similar gain. A panel or patch will work. Find a signal
source that isn't infested with reflections (including ground
reflections), Fresnel Zone issues, and is fairly stable (i.e. doesn't
physically move). Use Netstumbler, WirelessMon, or Kismet to compare
the signal strengths. For additional accuracy, use a step attenuator
to adjust the signal levels to a common reference level. Better yet,
use a spectrum analyzer.

Cranial self-depilation is not particularly useful for cleaning up a
Usenet news group. I'm not sure what filter he uses, but it seems to
work quite well.
<http://www.radiobanter.com/forumdisplay.php?f=4>
I sometimes wish he would add a sanity filter, but then there would be
nothing left to read in rec.radio.amateur.antenna.

Perhaps not an optimal one (which would be the geometric mean of the
source/load) but an effective one - if it were designed so (I don't
think it was ever intended to be one).

In fact the beads won't do that at all. They see only the common mode
circuit. Reflected power is going to reside in the transverse mode
circuit where the beads are invisible.

>heat) in the ferrite beads.

Ummm... I'd disagree (or at least quibble) on at least two grounds.

Ground #1: the ferrite beads would only block non-balanced current flow back down the outside of the coax. They will have no effect at all on power which is reflected back down the inside of the coax (the center conductor and the inside of the shield) from any impedance mismatch where the coax meets the folded dipole.

In effect, the presence of the beads (if they're choking the coax properly) actually ensures that the transmitter *does* see the true effect of any impedance mismatch. The transmitter is just as likely to see a higher SWR than a lower one, when the beads are added.

Ground #2: the beads do not necessarily result in a significant loss of power. If their RF impedance is high enough at the frequency of use, then RF current flow through them will be negligible, and there won't be a loss of power. Power loss in choke-ferrites tends to be worst when the RF impedance is both resistive, and too low for the application (i.e. still allows substantial current flow, which then results in dissipation of power inside the choke).

However, a 1/4WL side-by-side balanced run of 50 ohm coax with
a Z0=100 ohms makes an excellent match from a 200 ohm load
to a 50 ohm source.

Sure, as soon as I try to make you King you find work for me :-)

Ya, I have quad panel on the boat, when I get some time I'll try the
comparision.
BTW, I had a friend purchase an Alfa-Awus-036 Wifi Adapter.
He said it worked very well! So I ordered one, I replaced a TP-Link
TL-WN321G
with the Alfa-Awus-036. I had 23 signals received with only about 4 usable
signals on the
TL-WN321G. After I installed the Alfa I received 36 signals and all of them
have a signal
strength that would make them usable. (Of course some are encrypted)
This thing screams! I had used the TL-WN321G for several years and thought
it was good
until I tried the Alfa.
http://www.amazon.com/Adapter-Wardriving-Extension-Strongest-Market/dp/B000QYGNKQ/ref=sr_1
_4/181-2302073-2115203?ie=UTF8&s=electronics&qid=1257004388&sr=8-4
I'm using it with a 19dbi* panel antenna aimed a a 7 story condo.

I built several models of the antenna folded dipole assembly. The
simple rectangular rod folded dipole yielded about 300 ohms. A
slightly better simulation of the rounded ends, but still using a
round rod, was about 260 ohms. Converting it to a flat wire ended up
about 280 ohms. I never got anything even close to 72 ohms. It's my
<http://802.11junk.com/jeffl/antennas/mfj1800/>

Show my your NEC2 deck and tell me what I did wrong, and maybe I'll
believe that it's 72 ohms. Incidentally, the possibility that I
screwed up somewhere in the model is quite real:
<http://802.11junk.com/jeffl/antennas/mfj1800/mfj1800.txt>
(I'll convert this mess back to a macro form so it's easier to read
maybe this weekend).

Agreed, if there were a balun present. Without a balun, there's going
to be some radiation from the coax cable, presumably from the shield.
Disclaimer: I don't fully understand how baluns work, and certainly
don't understand what the piece of coax with ferrite beads on the
MFJ-1800 is suppose to do.

You lost me here. Just what are the beads suppose to do if not block
the reflected signal? Presumably, they do serve some useful purpose.
Now, you're suggesting that they could make the VSWR worse?

This is beginning to sound like the discussion about whether it's acceptable to use a high VSWR antenna. The standard answer is that if the transmitter can take it without going into protection or oscillation, then it's acceptable. I don't have a problem with that, although I've never seen a Yagi-Uda antenna with a 50 ohm coax hung directly onto a folded dipole because there are usually easy ways to do the matching and balanced to unbalanced conversion.

Digging a deeper hole, I've been assuming that if the ferrite beads were not there, the coax cable will radiate. After all, that's one purpose of a balun, to prevent coax radiation from mangling the pattern. That's still a dubious proposition due to the large length of exposed center conductor at both ends of the coax piece, which certainly will radiate some. I can add that to the model, but I don't know how to model the ferrite beads.

Doing it on a boat might be a problem. You're too close to the water which will probably be inside the Fresnel Zone. The water also acts as a great reflector. Thinks also move on a vessel, making stable readings difficult. I do my testing across a valley, where there's little chance of ground reflections (and there's a convenient 2.4GHz RF source from the local mountain top WISP). The path also has a wall of 40 meter high trees on both side to attenuate any interference.

>(I'll convert this mess back to a macro form so it's easier to read
>maybe this weekend).

I don't have an option of NEC2 deck. One thing you might check, and
is something I reported about, is does your model have the loop
symmetrical to the plane of the directors/reflector? I followed all
of Mike's dimensions and I note that your lobe characteristics don't
show his lack of driven element symmetry - mine do. Again, I have
modeled only the three elements (Ref/Dr/Dir) as the additional
directors are unlikely to perturb drive point Z as much as to push it
from 73 Ohms up to your high 200s (triple?).

Another point, as I have described, I used 1/4 inch diameter wire in
place of larger flat sheet metal elements (which I note you try to
replecate, but only once). True, 1/4 inch is not as big as any flat
dimension, but as Roy reports on equivalence, flat is not the same as
diameter, but flat performance is closer to a smaller diameter round
wire. Hence the 1/4 inch.

>Presumably, they do serve some useful purpose.

They block common mode current. That is their purpose as a CHOKE. A
good BalUn contains choking, but a choke is not always a BalUn. For a
quarterwave BalUn, the beads serve to isolate each end which is both a
choking AND a BalUn necessity. As the loop is isolated from the sheet
metal, isolation is preserved (allowing the section to "possibly"
serve as a quarter wave choke - neglecting the geometric mean of Zs).

>Now, you're suggesting that they could make the VSWR worse?

That is only a possibility, not a necessity.

>I've never seen a Yagi-Uda antenna with a 50 ohm coax hung

Yagis are often balanced by design. You should have seen 50 Ohm coax
coiled nearby the feedpoint as a choke (an alternative method to using
beads). If you have not, then you have probably seen an installation
that suffered degraded performance (and either to the operator's
unending grief, or to their total unawareness). You give some sense
of already knowing this with your comment that follows:

>Digging a deeper hole, I've been assuming that if the ferrite beads

I've written to that where I took exception to you modeling the Z as
series, and I pointed out it was shunt. Apparently you didn't follow
that comment.

You model the beads as either creating an open circuit, or adding a
huge resistance in-line. The net result to current is the same. The
long and short of it is that to model the exterior of the coax, you
add a wire of same length back to the choke section and call it a day.

>Jeff Liebermann

All that may be true, sorry King, is true.
My antennas are 14ft above the water and the signal only goes over water for
about 30ft
before a concrete parking lot fills the rest of the distance to my targets.
Total target distance
is about 600ft. The antennas are tipped upward about 10 degrees.
Here's the test I performed, I aligned the panel and the yagi on a pole
with about the 2ft between the yagi and the center of the panel. I aimed at
the target as
accurately a I could see. (Center of condo building) During testing I did
not terminate the unused
antenna.
I used net stumbler for signal strength numbers, I received 42 signals with
the Panel,
and 44 signals with the yagi.
The one signal I usually use went from -48db (panel) to -50db (yagi),
That's +2db for the Panel.
Then I did a Netstumbler screen print of the first 35 signals using the yagi
and then the panel.

I added all 35 signal strengths and divided by the 35, to get an average signal.
(35 is all that fit the screen without scrolling)
The Panel AVE = -58.11db, the Yagi AVE = 59.9db that is + 1.79db for the Panel.
So if you have any faith in my method, it looks like the yagi is down about 2db from the Panel.
I'm impressed, the MFJ-1800 yagi is advertised as a 15dbi antenna, the panel
as 19dbi antenna.
Here's the Panel seller for the 19dbi panel antenna.
http://www.fab-corp.com/product.php?productid=549&cat=255&page=1
At one time I found antenna plots for it, but can't locate them now.
Here's the yagi seller.
http://www.mfjenterprises.com/Product.php?productid=MFJ-1800
Thanks, Mike
PS.
Previously a saw 33 signals, I had never tried to optimize by adjusting the antenna, 33 was
good enough. While mounting the yagi I moved the position of the panel, looks like
I found a better position. :-)

A piece of coax, with several ferrite beads or cores around it, *IS* a
balun. It's a 1:1 "current balun".

It has the effect of ensuring that current flow into the radiator (the
folded dipole, in this case) is balanced - that is, the current
flowing into each of the FD's two feedpoint ends is equal.

>>In effect, the presence of the beads (if they're choking the coax

>Now, you're suggesting that they could make the VSWR worse?

Well, let's see. From your questions, and from your comment that you
don't really understand how baluns work, I suspect that there are
several aspects of what's going on here which are being "mushed
together". Let's tease them apart, with an example, and see if this
clarifies thing.

We're dealing with the following inter-related things: characteristic
impedance, VSWR, reflections, balance, RF flowing where you don't want
it, and feedline radiation.

Let's start with a simple example: a folded dipole (characteristic Z of 300 ohms), being fed by a twin-wire feedline (characteristic Z also 300 ohms), from a balanced RF source. RF is going to flow up the feedline... and the current at a point on each conductor will be equal-and-opposite that of the point immediately opposite it on the other conductor. The feedline is "balanced".

At each point on the feedline, the RF voltage and the RF current will be in a specific relationship, as defined by Ohm's Law (E=IR). Rewrite this as R=E/I, divide the voltage you measure by the current you measure, and you'll get 300 ohms as the result... this ratio is the characteristic impedance of the line.

When the RF reaches the folded dipole, it will "see" the same characteristic impedance and will flow into the dipole without any sort of disruption. Because the dipole is physically symmetrical, and (just as important) because there's nowhere else for the current flowing up either side of the feedline to go, the antenna is also balanced, and equal-and-opposite currents will flow into the two sides of the antenna.

This is a nice setup, electrically - everything behaves as if we would like.

Now, let's change the FD to a loop, with a feedlpoint impedance of around 100 ohms. That is to say, when current flows into the feedpoint, it must do so where the ratio of voltage-over-current is lower.

When RF flowing up the (balanced, 300-ohm) feedline hits the loop's feedpoint... well, we have a mismatch. The voltage-to-current ratios in the feedline and the loop will differ. The physical effect of this is that only part of the RF power successfully enters the loop. The rest is reflected back down the feedline, as a wave travelling in the opposite of the original direction. [The same thing happens when a radar wave in space hits an object - the impedance difference between free space and the material of the object reflects much of the power back towards its origin.]

The forward (original) and reverse (reflection-generated) waves will reinforce (constructively) and interfere (destructively) as they travel along the lines. At points where their voltages are in phase, the voltages will add and the voltage across the line will be higher. At points where they interfere (phases are opposed) the voltages will be lower. The ratio between these two (higher-voltage and lower-voltage) points defines the VSWR, and the transmitter will "see" this.

In this case, we have reflected power... and we have a VSWR of higher than 1:1. However, the whole system is still balanced - it's physically and electrically symmetrical.

Now, let's set that example aside for a moment, and look at another one.

Let's consider a simple dipole (center-fed, non-folded), with an impedance of 72 ohms. This is a physically symmetrical (balanced) antenna.

Let's feed this with coax, having a characteristic of 72 ohms.

Is the coax balanced? Yes and no. In one sense, it's balanced... if you look at the current flow on the inside of the coax, you'll find that the flows on the center conductor, and the inside of the shield, are equal-and-opposite. Also, the EM fields created by the RF flow are entirely within the coax (if the shield has full coverage, as in a hardline), which means that RF doesn't "leak out" and inteference has a hard time "leaking in". This is why you can run coax through conduit or next to metal objects without causing problems.

In another sense, though, the coax is not balanced, because it consists of *three* conductive surfaces... the center conductor, the inside of the shield, and the outside of the shield. When current flowing up the coax reaches the end (e.g. the antenna feedpoint), the symmetry can be broken:

- Current flowing up the center conductor has only one place it can go - to one side of the antenna feedpoint.

- Current flowing up the inside of the shield has *two* paths to which it can flow. It can flow into the other side of the antenna feedpoint, *and* it can "wrap around" the end of the shield and flow back down the outside of the coax. It will tend to do both, in a complex ratio which depends on the impedances that it "sees" for each of these two paths.

RF flowing back down the outside of the coax will generate radiation, which will add to / interfere with the RF radiatiating from the dipole. This will tend to alter the antenna's pattern somewhat.

In this example (72-ohm coax connected to 72-ohm dipole), we won't necessarily see an even current flow into the dipole, with a nice clean 1:1 VSWR on the line. We can still see some reflected power.

Why? Because of the "third wire" - the outside of the coax. Its impedance will appear in parallel with that of one side of the dipole... it will 'accept' some RF current (in effect, diverting it from its side of the dipole) and this will alter the feedpoint impedance of the antenna system. The imbalance of the coax (the presence of the "third wire") has disrupted our nice pretty theoretical picture. We've got more current flowing into the center-conductor side of the antenna (where there's only one path) than we have flowing into the other side (since part of the current has been diverted to flow back down the outside of the coax), and the antenna is no longer behaving in a balanced fashion.

How do we prevent this from happening? By using a balun... a device which has an unbalanced (usually coaxial) feed on one side, and which *forces* an electrical balance on the other side. Some baluns force

equal-and-opposite voltages on the two terminals on the balanced side, while others force equal-and-opposite currents on either side.

Some baluns are designed to present the same impedance on each side (1:1 baluns) while others are designed to have different impedances connected to either side (the 4:1 balun is the best-known).

A series of ferrites, clamped around a coax, are a simple (and often very effective) form of current balun. There's no impedance transformation built into this design - it's a 1:1 type.

How does this "choke balun" create balance? Quite simply: it blocks current flow on the "third wire" (the outside of the coax) by placing a high RF impedance in series with any current flow on this path.

As an example: consider the 72-ohm coax-and-dipole example. Let's assume, for the sake of argument, that the RF impedance seen along the outside of the coax (the "third wire") is on the order of 100 ohms or so (not unreasonable if it's a couple of wavelengths long). Without a balun of some sort, there's going to be a fair amount of current flow back along this "third wire", because the impedance isn't all that much higher than the 36 ohms (that of one-half of the dipole) in which it is in parallel with.

Now, let's clamp a few nice ferrites onto the coax. These add *lots* of inductance to the "third wire"... for the sake of argument let's say it's on the order of 1000j ohms.

All of a sudden, the third wire presents a *much* higher impedance at the feedpoint than it used to... it's 30 times as high as that of the dipole segment to which it's connected. Only a tiny amount of current can flow into the "third wire".

Since the current flowing up the inside of the feedline is balanced, and since the current reaching the feedpoint now has only one place it can go effectively (into the antenna), the current flow into the antenna is symmetrical - balance has been restored. Because the feedpoint impedance is no longer being significantly affected by the "third wire", we see almost exactly a 1:1 VSWR.

If we've added enough inductance (or enough RF resistance) to the "third wire", and choked off the current flow to essentially nothing, then the power loss in the choke is negligible... because there isn't enough current flowing to generate power to dissipate.

>This is beginning to sound like the discussion about whether it's
>acceptable to use a high VSWR antenna. The standard answer is that if
>the transmitter can take it without going into protection or
>oscillation, then it's acceptable.

I think that's oversimplifed a bit. I think there are really three factors to consider:

- Will the transmitter be stable and happy (not self-protect, not oscillate, not burn up)?

- Will the transmitter actually deliver full rated power (or close to it) into the impedance that it "sees" as a result of the higher SWR? This impedance may be lower or higher than its rated load, and may have significant reactance in it.

- Will the additional ("excess") losses in the transmission line, as a result of the higher current at some points, be a problem?

> I don't have a problem with that,
>although I've never seen a Yagi-Uda antenna with a 50 ohm coax hung
>directly onto a folded dipole because there are usually easy ways to
>do the matching and balanced to unbalanced conversion.

The "Cheap Yagi" design is the closest to that... a half-folded dipole, with the directors and reflectors positioned so that the HFD has a 50-ohm feedpoint impedance. Direct coax connection (ferrite bead is optional).

>Digging a deeper hole, I've been assuming that if the ferrite beads
>were not there, the coax cable will radiate. After all, that's one
>purpose of a balun, to prevent coax radiation from mangling the
>pattern.

It could radiate, depending on the length of the coax.

> That's still a dubious proposition due to the large length
>of exposed center conductor at both ends of the coax piece, which
>certainly will radiate some. I can add that to the model, but I don't
>know how to model the ferrite beads.

I believe you'd want to model the coax balun as a combination of two elements: a pure transmission line, and a "third wire" connected at the antenna feedpoint and running back parallel to the transmission line (this being the effect of the outside of the coax).

To model the ferrite beads, add a lumped impedance in series with the third wire, at the point at which it connects to the antenna. As a wild-and-almost-certainly-wrong SWAG, try adding 100+100j (to mimic the purely inductive, and the lossy-resistive aspects of the ferrite).

No problem. Just post or email me the .EZ file. 4NEC2 will import it
or I'll just switch to EZNEC. (I promise not to complain about your
using inches).

>One thing you might check, and
>is something I reported about, is does your model have the loop
>symmetrical to the plane of the directors/reflector?

Unfortunately, yes. I got lazy and planted the folded dipole centered
about the axis of the other elements. I don't think (guess) it would
make much difference, but I'll move it to the correct position this
weekend.

Got any theory as to why the vertical and horizontal patterns are so
different? That only appeared when I switched to the flat wire folded
dipole. They were symmetrical with the wire rod driven element.

>I followed all
>of Mike's dimensions and I note that your lobe characteristics don't

>directors are unlikely to perturb drive point Z as much as to push it
>from 73 Ohms up to your high 200s (triple?).

Yes, something is different. In past tinkering, I've found that 3
elements is sufficient to characterize the feed impedance, where the
additional elements just improve the gain and pattern.

>Another point, as I have described, I used 1/4 inch diameter wire in

>wire. Hence the 1/4 inch.

Well, I used a rod with the same circumference as the flat
(asymetrical) elements. Methinks the element diameter would have an
effect on the bandwidth of the antenna, but not on its characteristic
impedance.

The folded dipole is going to have about 4 times the impedance of a
plain old dipole.(POD) In this case if you used a POD with your yagi
antenna the feedpoint impedance would be in the neighborhood of 10
ohms
with a folded dipole it will be more like 40. Not a bad match for 50
ohm coax

Hi Mike,

The driven loop is not symettrical to the plane of the directors and reflector, thus it peers down (or up, or to the side - depending on deployment).

Look boresight down the boom. The loop is off-center.

Good, I thought that might be the answer but wanted to check.
Glad I added that detail to the drawing, do you think that is
engineered to control output impedance?
What happens to the impedance if you center it?

Could you post your model or send it to me, I have a fellow
ham that tried to model the FD and could not get it to work.
He would like to see one that does work and find out what he did wrong.
Eznec if you have it.
Thanks, Mike

Hi Ronald,

If you mean by "dummy load" something with a 50 Ohm match and
resistive (somewhat redundant to the 50 Ohms) then it has to be a
resistor (department of triple redundancy).

Finding a resistor that is sufficiently power rated is not a simple
(cheap) chore. Making your own will take time and ingenuity.

Consult:
Caddock Electronics, Inc.
17271 North Umpqua Hwy
http://www.caddock.com

for resistors that will fill the bill - once you build the heatsink.

An LC circuit won't make a good dummy load.

A "pure" LC circuit is lossless... both the L and the C are pure reactances, and neither will (or can) dissipate any power.

In practice, you could make an LC series circuit which would be 50 ohms resistive at a single frequency... you'd use a really lousy inductor (one wound with many turns of small wire) which has a pretty significant DC resistance. The series C would be just enough to tune out (resonate) the inductance at the frequency you're going to be using it with. The inductor's ESR at this frequency is going to be higher than its DC resistance, due to skin effect and other loss phenomena.

The resulting circuit would *not* be 50 ohms resistive at other frequencies. It'll have a capacitive reactance at lower frequencies and an inductive reactance at higher frequencies.

Seems like an expensive and annoying way to make a dummy load. Unless you've got other requirements you haven't mentioned, I'd suggest just making a halfway-decent dummy load from a bunch of noninductive resistors (e.g. in series-parallel) mounted on some sort of heatsink.

That is because the only criticism was the same as my great
grandaughter would utter, because she lacks the logic of explaining
why! More than 6K viewed my post on the double helix antenna with no
where near the reliance on spam as as with this group.
It was for that reason I have placed a thread, on record, on how to
make the smallest radiator possible which is in contrast to the Yagi
design and where I also stated a theorem for radiation to which the
most efficient non electrical wavelength radiator conforms .

What a king says is by definition true, even if it's wrong.

>My antennas are 14ft above the water and the signal only goes over water for
>about 30ft
>before a concrete parking lot fills the rest of the distance to my targets.

Sounds good. You're out of the Fresnel Zone and the parking lot isn't
going to contribute any reflections.

> Here's the test I performed, I aligned the panel and the yagi on a pole
>with about the 2ft between the yagi and the center of the panel.

Not so good. You can't leave a bunch of potentially resonant metal
hanging around that close to the antenna. The unsused antenna could
easily be re-radiating anything it pickups up from the other antenna.
One antenna at a time please.

>I aimed at
>the target as
>accurately a I could see. (Center of condo building) During testing I did
>not terminate the unused
>antenna.

Ugh. If you're shooting into what's essentially and indoor wireless
router, you're going to get reflections from the building and in
particular, from the room where the AP is located. Also, not so good.

>I used net stumbler for signal strength numbers, I received 42 signals with
>the Panel,
>and 44 signals with the yagi.

How steady were the readings? With my experience with Netstumbler, if
I wait a few minutes, the readings will move around perhaps 2-5dB. Are
you doing this on Channel 6 (middle of the band) or near the band
edges?

>The one signal I usually use went from -48db (panel) to -50db (yagi),
>That's +2db for the Panel.

>(35 is all that fit the screen without scrolling)
>The Panel AVE = -58.11db, the Yagi AVE = 59.9db that is + 1.79db for the
>Panel.

Good idea but not really valid as you're probably measauring the side
lobes of the antennas. An antenna with many side lobes is going to
hear more stations than one with just a single major lobe.

>So if you have any faith in my method, it looks like the yagi is down about
>2db from the Panel.
> I'm impressed, the MFJ-1800 yagi is advertised as a 15dbi antenna, the
>panel
>as 19dbi antenna.

I have less faith in the RSSI linearity of thatever you're using for a
wireless device. -50dBm isn't particularly saturated, so presumably,
the comparison is valid. There might be some gain compression at high
signal levels, which explains why you're seeing 2dB difference instead
of 4dB. I would have predicted a larger difference as my NEC model of
the MFJ-1800 predicts a gain of about 13dBi. I would have expected an
even larger difference.

Ok, measuring antennas is never easy, I'll hopefully get some time next
week.
I won't bore you with the details, but the campaign I'm running is
eventually going to have the party overthrow a king. :-)
I'll install one antenna at a time.

I didn't see any changes but I only paid attention to the one signal I
normally use.

I received on the channel the source transmited on.

Here's a file of the two screenprints with channel and signal strength.

http://i395.photobucket.com/albums/pp37/Qmavam/Comparisionofwfiantennas.jpg

For what its worth.

Who knows, I think the whole condo is in the major lobe and nothing but
water

on one side and on the other side I doubt there are any signals. I do recall
one -80 db

signal so maybe something in the side lobe.

>>So if you have any faith in my method, it looks like the yagi is down

Measuring antennas is never easy.

I note my laptop within 20ft of the router has a -36db signal using
netstumbler.

Thanks for your help Jeff,

Mike

Thanks to Richard too.

You claim amazing properties for your designs, and yet either you won't
tell us how to make them, or in this case, they are nonsensical junk.

And they are accompanied by made up physics, which is, at least,
entertaining science fiction.

Ah yes, Art Unwyn, SciFi master.

What is lost in this review of the frailty of our patent system is the
destructive interference
of what we refer to as justice. Not only does law change with the
current meaning of the word in this country other countries ensure
that the intent of the written word is determined
at the point that the law is made. It is for this reason that the U.S.
has more lawyers than any other country as all laws as with the
written word changes with the passing of time. At least in the eyes of
experienced debaters. Another deterent to fairness of patent
protection
is that other countries has that the "loser pays ALL costs generated
by the suit" !
In the U.S. for some reason each pays their own costs regardless if
the charge was malicious or not. Thus we have a continuance of suits
and countersuits depending on the finances of both or the amount of
money that can be made during the generated passing of time. Many
examples of this can be seen in the many pharmacutical cases.
Worst of all, with respect to fairness in the protection of patents,
is when the true owner of a patent has not the funds such that he can
keep pace with the challenger such that the time comes when he has not

the funds to appear in court and thus the challenger unjustly wins his case. Not on the merits of justice but on the amount of funds he is willing to spend compared to the losses incurred by violating patent law.
Present patent law attempts to combat these problems by giving prime responsabiulity to the PTO but we are finding that justices resent this action and are more than willing to accept cases where they gain back their original powers.which is not always dependent on justice.
From the congressional side of any so called change in justice, one cannot ignore that the patent system is a "cash cow", revenue that any congress is not willing to give up as part of his rescources for spending.

3207. Cobwebb element formula??

Newsgroup: rec.radio.amateur.antenna

Is there a formula to set the gamma match on a Cobwebb type element??
as I have built a Cobwebb ant for the higher shortwave broadcast bands
using normal unmatched dipoles (468/f) but I don`t think it is optimal hence
the need to gamma match!!

Regards.

Lee ...G6ZSG.

3208. The antenna of AC7JF?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-23 00:32:47 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <48idnR8BXqaoRZTWnZ2dnUVZ_tKdnZ2d@bright.net>
Source record: 11920

Dear Group:

A long time colleague of mine, who was once my student and is now retired, is also a great fan of antennas. While driving around Lake Havasu City, AZ, looking at antennas - do we not all do that when we travel - he spotted (and photographed) the antenna of AC7JF.

The antenna can be seen at: docpg.org

The antenna appears to have four, yagi style elements, to be feeding one element with a second element connected to the driven element with a transposed TL, and appears to be using stubs on the ends of the elements to effect tri-band performance.

Hy-Gain uses a similar scheme on one of their verticals.

I think that I have seen this antenna before, but I can no longer place it. Any suggestions?

It's a bit hard to see, but it looks like the feed (left to right in the
picture) is to the 2nd element with a crossed phase parallel line to the
third.

Probably this one:
http://www.hamanuals.com/MMans/KLM80.pdf

A KLM-34A.

I am not sure why they went out of business, but they seemed to make good
antennas. I have the OSCAR combination of the 2 meter and 432 mhz system.

Dear Ralph Mowery, KU4PT:

Spot on! Thanks.

Complicated antenna. Would be a big challenge to model.

73, Mac N8TT

This might explain some of it:
<http://www.qsl.net/wb6jnn/middle.htm>
"Unfortunately, the Ham Radio business isn't as lucrative as most hams
think it is, especially for a U.S. based manufacturer. While Japanese
companies have all of their million plus ham market plus Europe plus
the U.S., we had only the domestic market which at that time was not
in a growth mode. KLM was sold to a new owner in 1979. It later sold
again and ultimately adopted the Mirage label for its amplifier line
(based on Ken Holladay's designs, originally) and has since then split
up to seperate owners for the antenna and amplifier businesses. The
KLM antenna line, in fact, disappeared abruptly late in 1999."

Yes, it's for a single frequency. Since an antenne is also a LC-circuit
that doesn't get warm but radiates in fields.

I had it all open built so i suspect mantelwaves etc. But on paper a series
LC circuit forms a loading of a particular Zo. This statement is still right?
Lets say an input on a semiconductor p.a. stage with an LC series circuit..

Ronold,

Your discussion gives every impression that you don't know
1. what a dummy load is
2. what it is for
3. why it is principally resistive.

Your statement above is true on the face of it, but has no meaning
beyond a tautology: you don't use a dummy load IN a p.a. because you
don't use a dummy load in a p.a. So what?

So, the direct answer to the question in the Subject line:
How can one make a dummyload from a LC circuit ?
is:
You don't

You seem to be hedging around another purpose but don't want to tip
your hand. Obfuscation does not help find answers.

The only reason that works is that the transmitter has a protection circuit that detects high VSWR and either reduces power or shuts down. The idea is to not destroy the output xisitors. Into an infinite VSWR load, you can easily find twice the collector voltage across the output stages, which on many radios, will destroy the xsistors. With other type of loads, the output stages could easily draw twice their rated current, this time destroying them with too much dissipation.

Judging by your wording, I don't think you have a clue what a dummy load does or where to install it. It's not "in" the PA stage. It's after the PA, after the low pass filter, after the T/R switch, and in place of the antenna. You use a dummy load for testing and measurement so that you don't pollute the airwaves or fry your radio tuning into an unknown load.

>
> Not dissipate but surely radiate in a closed box!

It will not radiate efficiently.

The radiation resistance of a physically-small coil is going to be
very small... a small fraction of 1 ohm. What your transmitter is
going to "see" will consist of:

- The radiation resistance of the circuit (probably less than 1 ohm),

in series with

- The loss resistance (mostly in the coil)

in series with

- Whatever reactance remains after the series L and C resonate against
one another.

If the coil is "perfect" (lossless) and the L and C reactances are
equal and opposite, then all you'll be left with is the radiation
resistance.

If it's in a closed (shielded) box, matters get *worse*. The presence
of the reflections from the walls will reduce the radiation resistance
even further.

Will your transmitter be happy with a load which looks almost exactly
like a short circuit to ground.

> Yes, it's for a single frequency. Since an antenne is also a LC-circuit
> that doesn't get warm but radiates in fields.

And it radiates with reasonable efficiency, precisely because it's
physically large - it has a substantial radiation resistance.

This will not be the case for a physically-small LC circuit.

> I had it all open built so i suspect mantelwaves etc. But on paper a series
> LC circuit forms a loading of a particular Zo. This statement is still right?

No, I don't think so... at least, not in the way that you think.

If you show us the specific circuit you're thinking of (components and
their values, wires, and desired operating frequency) we can analyze it.

> Lets say an input on a semiconductor p.a. stage with an LC series circuit..

A series LC circuit is not, by itself, going to present a resistive
impedance.

> Suppose we feed 20 watts in a p.a. but don't want to use a dummyload
> in the p.a. Come on this is done all the time.

Sure. If one does not want to have a dummy load in the PA, one uses
an *external* dummy load.

A dummy load, almost by definition, is something which accepts RF, and
dissipates it as heat. An ideal dummy load doesn't radiate at all. If
it does radiate significantly, we call it an "antenna".

One *cannot* magically make those 20 watts disappear. They either
have to be radiated (out into space) or converted to heat and
dissipated.

A small LC circuit will not do a good job of either of these things...
won't radiate efficiently and won't have enough resistance to act as a
comfortable dummy load (e.g. Zo near 50+0j).

Lee,

The "bent dipole" elements used in the CobWebb have a low feedpoint impedance - around 10-12 ohms. So the elements are formed as "folded dipoles" to get a 4:1 impedance transformation and raise the feedpoint impedance close to 50 ohms.

When you use "twin flex" for those elements you have to place the shorting links in the right place to account for the **differential-mode** velocity factor of the cable; otherwise you create two low reactance stubs which shunt the feedpoint and modify the impedance.

Take a look at the detailed description on my web site and PM me if it's not clear:

http://www.karinya.net/g3txq/folded_dipole/

You can avoid the need for folded dipoles entirely by using single-wire elements and putting a 1:4 current balun at the feedpoint. Here's how I did it:

http://www.karinya.net/g3txq/cobweb/

Done all the time, but usually with resistive loads.

Could you elucidate exactly why you want to do this? I can't think of any good reason to use LC. I suspect you might have some terms and principles a little mixed up.

A dummy load is used to absorb RF power at the end of the transmit circuitry. The transmitter does everything it's supposed to do, but the power goes into the dummy load, and is dissipated as heat. Ideally no RF makes it out of the load.

The ideal impedance for a transmitter is resistive. For that nothing can beat a resistor.

All amateurs here who i suppose 'believe' to much. Do you go to church
every sunday ?
- sometimes dummyloads are used in input stages of a valve or mosfet p.a.
because valves and mosfet only use the rf voltage NOT the power.
So the driver stage (xmttr) has to be dummyloaded and tapped.
Understand ?
-Then the remark : " a LC circuit won't radiate efficiently " . So what?
Thats exactly what i need here.
- so every LC series circuit you see in schematics, ï¿½f you see them, you call
shortcuts ??
- If you use an antennatuner for a 'nittingneedle' you will get a 1:1, and we don't care
the
bad radiation pff, and that antennatuner has a series LC circuit inside !!
So no shortcut at all, dummy.
So whats your point ? I only asked about the practice of the consept.

I see its easier the become doctor in the usa then farmer in Belgium ...

> So the driver stage (xmttr) has to be dummyloaded and tapped.
> Understand ?

Sure. And, if those are truly "dummy loads", they are *not* simply LC
circuits. They have a resistor of some sort incorporated into them,
which is responsible for providing the correct termination impedance
and which serves to dissipate the power from the driver stage.

In other cases, what you call "dummy loads" for driving a MOSFET are
not simply "dummy loads". Rather, they are impedance transformers,
to step up the RF voltage to the correct level needed to switch the
MOSFET or tube properly.

In many cases, an LCR input stage to a final amplifier may have both
of these functions... impedance transformation *and* load termination.

> -Then the remark : " a LC circuit won't radiate efficiently " . So what?
> Thats exactly what i need here.

In standard radio technology, a "dummy load" is a device which
dissipates most of the power fed to it.

An LC circuit isn't one. You *need* something with resistance in it,
if you want to terminate the driving signal properly (i.e. dissipate
its power).

> - so every LC series circuit you see in schematics, f you see them, you call
> shortcuts ??

How in the world did you come to that ridiculous conclusion? Please
don't put words into my mouth.

LC circuits have *many* useful functions in a radio schematic. Two of
the primary ones are impedance transformation (matching), and
filtering (bandpass or notch).

Acting as a dummy load (in the accepted sense of the term) is *not*
one of the good functions of an LC.

> - If you use an antennatuner for a 'nittingneedle' you will get a 1:1, and we don't care
the
> bad radiation pff, and that antennatuner has a series LC circuit inside !!

That antenna tuner has an LCR in it. The "R" is the loss in the coil... as I pointed out several postings ago, a coil does have a loss resistance.

In the case you're talking about, "matching" a nitting-needle load with a typical T-configured antenna tuner may result in an apparent match. What's happening, is that you're creating a rather high-Q resonance inside the tuner... and all of the power is being dissipated in the coil's loss resistance. Very little of the power is actually going into the load - it's not really "matched".

The coil heats up, and (if you've got a cheaply-made tuner) you melt the coil form and burn up the tuner.

The problem with depending on this sort of circuit (e.g. using a coil, and a couple of capacitors) to dissipate power (acting as a very crude sort of "dummy load") is that it's unpredictable, dangerous, and inefficient.

It's unpredictable because the series resistance of the coil is typically not specified by the manufacturer. In fact, the better the coil (heavier wire, open-spaced windings) the lower the series resistance and the losses, which means that you have to use a higher-Q tuning (more critical adjustment) to establish the match.

It's dangerous, because the sort of small coils you'd normally find in the driver-to-final network of an amplifier can't dissipate the amount of power you're talking about (20 watts). They'll burn up.

It's inefficient, because for the price of one adjustable coil which can be tuned in this way (with a couple of capacitors), will give the correct termination impedance (typically 50 ohms), and not melt down or catch fire or otherwise self-destruct, you can buy *dozens* of very well made 50-ohm noninductive resistors, which will give a good flat termination impedance over a *much* wider frequency range than a high-Q resonant circuit. Such resistors will be cheaper, smaller, and more reliable than a lossy-LC-circuit kluge, and won't require any tuning at all to work properly.

> So no shortcut at all, dummy.
> So whats your point ?

My point is, you're attempting to choose the *wrong* technical solution for your problem. You'll waste money, and end up with a device which is bigger, tricker to tune, and less reliable than is necessary.

> I only asked about the practice of the consept.

And, the accepted engineering practice of this concept is "This is a bad idea, we don't do it that way. We use resistors."

Yep. The photo looks like the original by KLM known as the KT-34. The
shorting bars are heavier (thicker) on the version currently made by
M2, known as the KT-34M2. See:
<http://www.m2inc.com>
<http://www.m2inc.com/products/kt/kt34/kt34m2.html>
<http://www.m2inc.com/products/klmaddon/index.html>
Better photos:
<http://n4zi.net/kt34xa_upgrade_page.htm>

Mike Staal (W6MYC), one of the founders of KLM, runs M2
<http://www.cq-vhf.com/M2AntennaFall06.html>
and might offer some assistance.

Doing a bit more Googling, I found plenty of detail at:
<http://lists.contesting.com/archives//html/towertalk/2008-04/msg00135.html>
<http://lists.contesting.com/archives//html/Towertalk/2008-03/msg00478.html>
which indicates that a model may be a challenge:

> For entertainment, and with low expectations, I put together a model of
> the KT34A using MMANA, recognizing that, for free, you cannot get high
> quality results. I can supply the input file if anyone is interested.

Hi Mike,

The best evidence is from his postings. If there is a language
difficulty (we've been assaulted with paisano fruit seller dialect
from Italy when this is obviously Hollywood clichï¿½) then Ronald's
re-characterizations expressed in understood English are not
miscomprehensions of language.

Ronold: "A dummy load is an LC circuit."

anyone else: "A dummy load is NOT an LC circuit."

Such an interchange is more seriously logic limited if
"misunderstood." I think Google translate would cope easily here.
Negating the original phrase does not lead to the sophism of doctors
and farmers - trolling does.

If you want to be gracious, we have a Belgian CBer who is trying to
work 40M. That level of technical ability is NOT masked by
translation.

Reminds me of the dwarf's argument in the movie "In Bruges."

I am the overseas sales manager of JOYHOLD GROUP LIMITED,which is a PCB (Printed Circuit Boards) manufacturer in Guangzhou,China. I write this letter to you as an introduction and extension of our hands of friendship and establishing a meaningful business relationship with you.

Following is our information:
We locates at Guangzhou City, Guangdong province, China. Our main service is developing, producing and marketing the high quality Single sided,Double Sided and multilayer printed circuit board.

We are UL(E306819) certified manufactory of Printed Circuit Boards. We focus on the quick turn prototype, small quantity and mass production in Double Sided and Multilayer PCB(1-20 layers).
1. We can provide Fr4 High frequency board, backplane, thick copper PCB and Metal base board(AI, Cu).
2. We can do surface as (lead free) HASL, Immersion Gold, HASL LF, Flash Gold, OSP.
3. We can print solder masker with green, red, yellow, black, blue, matt, and white colors.
4. We have perfect sales system and after service system with quick respond and good communication.
We hope to establish longtime and friendly business relationship with you. Good quality, reasonable price and the 5-Star service are guaranteed.

If you have any PCB to purchase,please contact me when you free.

Best regards,
Ziv.Lee

3235. Looking for matching transformer.

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-26 08:51:48 UTC
From: Lostgallifreyan <no-one@nowhere.net>
Message-ID: <Xns9CCF5A293F21Bzoodlewurdle@216.196.109.145>
Source record: 11946

Originally posted to rec.radio.amateur.misc as advised by guidelines read in a monthly posting, but got no help there apart from a suggestion to post here...

This post has more to do with a firm selling radio stuff than the stuff itself, and their apparent want not to do business even with people who send on-topic and polite emails at infrequent intervals. That's strange, so I want help with that from someone who HAS done business with them, or knows something about why they refuse to answer a normal sales inquiry.

[Original message]
Hello, I'm after an antenna matching transformer from http://www.iceradioproducts.com and being in the UK, I need to ask them for shipping costs, and whether they take PayPal, as these are crucial matters for arranging international transactions with different currencies. They provide an email address, 'sales at TheirDomain.com' (Did that because I don't want web-archive spiders and Google-gropers to find that and spam it to hell). I've sent three polite, short requests to that email over the last 8 days or so and can't raise a response! Odd given that they supposedly want business. Can anyone reach them personally for me? Or perhaps point me to a UK supplier of what I'm after?

What I want is their 'Beverage' matching transformer 180A, or perhaps 183A for greater range at the longer wavelength end, (down to 100 KHz or so). I'm also trying to find John Doty's plans for winding my own, but the only mail addresses I've found for him so far have gone the way of the Norwegian Blue. John Doty says that the 180A is so good it makes good sense to buy it anyway, but right now I'm not at all sure I ever will without help.

For the record, because there might be some people who will assume I damned myself and deserve no reply if I didn't get one right away from the people I tried to reach regarding that matching transformer, I insist on advancing a clarification so that such prejudice never arises. Below is a sample of the actual email to the firm I'm trying to buy it from. I'm doing this to make it absolutely clear than I am not a vulgar troll that deserves a total lack of response. If I get no response, so be it, but it had damn well better NOT be due to foolish prejudice. I don't mean to offend anyone here with this attitude, it's just that seeing the way business is often conducted in the electronics groups these days, I don't want that nonsense to prevent someone with a working brain from understanding that I need a helpful response, and I wonder if I don't head that nonsense off before it starts, it might happen anyway. I doubt people who resist that indulgence will feel offended by this post. What I'm trying to show is that as I have tried to research exactly what it is I need, and can demonstrate this, it is singularly odd that a professional firm selling exactly what I want fails to respond!

Sample of mail to http://www.iceradioproducts.com sales address follows:

Hello, I sent an email a few days ago but have no answer. Please answer me. I also need to know if you will take Paypal payments, as I can't otherwise think of an easy way to pay you in USD. (And I think it's actually the 183 that I'll need for wider range but the price is the same. If it's economical to ship, I'm considering two of them so I have backup, as one will be at moderate risk of weathering.

[Original message]
Hello, I'm interested in the matching transformer unit named in the email subject. Please tell me approximately what the cost is to send to the UK. And thankyou for using USPS. It's good to see that, after recently having to turn away from a great auction because a seller refused to ship with anything but UPS who in my experience are a bunch of mercenary ripoffs. FedEx by comparison are angelic, but I prefer to trust USPS and the Royal Mail, recorded. They rarely fail, and never overcharge.

In case you're wondering, I found your transformer in a web page archiving some old Usenet posts, while looking into 'MLB's to match a long wire to a 50ohm coax to improve shortwave recpetion. A guy called John Doty at MIT posted stating that your transformer is a better buy that the RF Systems 'original' MLB, and that of another firm, and from what he says in the message I think he is likely right.

A logical conclusion arises - they are out of business.... (They is
probably he, as this is in all likelihood a one-man operation.) With
a page that hasn't been updated in two years, there's every impression
not all the lights are on in that office.

Thanks for substantiation of this being very old. Your archive
reveals the message you rely on is 14 years old. There have been two
economic collapses since and a couple of wars (African/Balkan
genocides too).

You would be better served going to more active producers of matching
transformers priced in Euros. In this forum they are tolerated as
placebos.

Cheers,
The Master

Ah, I might have been you, you know. :) Lost, but never said which one.. It's
an old handle, I chose it because it was likely unique, never have to wonder
what to use on the web with that so the habit stayed. It's anon, but anon
doesn't always mean nuisance. I'm not asking for much, just some lead to
figure out if those transformers really are as currently available as they
appear to be. Once I have to shell out money I won't be anon. :)

Anyway, thanks for the reply. That post was 14 years old, but I did check out the transformer, the ICE Radio Products site still exists, it doesn't look old, let alone dead. They have a setup to take orders and receive secure payments. Only reason I didn't do that (wisely, it seems) is that I had to ask them to confirm details before I did so, and they aren't responding at all. The simplest explanation is they don't like outsiders to the US, period, and just won't acknowledge their (our?) existence. Would be a tad strange an attitude for people specialising in long distance radio, though.

The rambling cloth was something maybe I could have cut, but I went by instinct. I could either appear as a newcomer with a tiny terse question that might fade to oblivion in half an hour, or include enough context to make it memorable. Having drawn such a blank until you replied, I thought I might as well go for broke. Someone might see this, and also be someone who knows why I cannot reach that firm and buy that transformer. Or be someone who has a copy of John Doty's plans for winding our own... The extra protection built into the ready-made one, plus the build quality overall, means it's a good choice, so I want to get one. If you (or anyone else) knows a European source of a direct equivalent to the ICE 183A (or 180A) 'Beverage' matching transformer's spec, please point the way. I did try Googling at the end of a long day of Googling, so I ought to have picked up leads if they were easy to find. Most I did find were the non-isolating 'MLB' type 'baluns' that aren't really baluns, not what I'm after at all, in light of that 14 year old article which is technically surely current, given the misconceptions I encountered before I found it.

Hello Companion,

As I pointed out, you probably can do just as well closer to home - if
you can set the appropriate coordinates in the TARDIS.

>Anyway, thanks for the reply. That post was 14 years old, but I did check out

You have missed the point of a one-man-show. The website (if the
business is functional) is running on automatic. Emails are not the
conventional method of transaction.

As to the currency or correctness, that is a gamble. Many claims are made that go unchallenged, or worse, unverified. In this forum, you would be miles ahead if you simply specified your needs and let the chips fall. It saves time compared to first having to disillusion you, and then to re-educate you.

The first point of wrenching disillusion is there is no one-size-fits-all matching. Once you get past that, we generally have to drag out of you what "would do" once you relax your expectations of a supposed perfect solution. Much of that grief is shunted aside if you simply say what you require. [Citing a popular model only puts the grief back on the table.]

...

Just checked their web site. Their contact info lists "help@..."
instead of "sales@..." as the email address. Have you tried that?

My impression is that it's a pretty small operation. It might
literally have a staff of one. Who knows what might have happened--
vacation, illness, ...

I'd be a bit careful about ordering anything from a company that lists
so few specs on their equipment. I checked the "receiver preamps"
page and found no mention of some pretty important stuff like third
order intercept, noise figure, and some details of the filter
performance for the "single band" preamps.

Cheers,
Tom

I took my son out to watch the ISS (International Space Station) pass by
at 5:43 this evening. My son saw it first but we weren't sure because
something else was moving at the same speed. We quickly realized
yes both objects were moving across the sky. At arms length they were
about thumb to pinky (spread out) distance apart.
When we got home I started looking online to see what the second
object was. Turns out to be STS129, the space shuttle!
Open these in two different tabs and see how close they are to each other.
The ISS.
http://www.n2yo.com/?s=25544

The Space shuttle.
http://www.n2yo.com/?s=36094

I don't know how long they will track.
Well, I know not past 9:30 tommorrow,
the shuttle is supposed to land.
Mike

This must have been a rare occurance, look how close the were.
Maximum altitude is at ISS 17:44:57 STS 17:45:19 Within 22 seconds
Altitude ISS 37° STS 38°
Within 1°
Azimuth ISS 44° STS 44°
Same
Distance ISS 549 km STS 545 km
Within 4 km.

```
ISS = International Space Station STS= The Space shuttle- STS 129
Mike
```

Try this. It shows other birds that will be in your view. Remember
brightness is an inverse scale. Something negative is very bright.

Yes, That's what I used to find the ISS would be coming over.
Then when we saw two objects, I tried to get back on that sight
and it was to busy for the next few hours.
Mike

My cellphone was close enough, but a compass would have helped
pinpoint the rising direction better. 4 hours later and I'm still excited!

http://www.cammenga.com/cammenga-products.php?category=1
The phosphorus version is good enough. I "juice it" with a flashlight since I'm not working SWAT or special ops. ;-) You can pay extra for tritium, but it wears out. You shouldn't buy one used for that reason. The phosphorus version is under $40 and it will last a lifetime, or until it is lost or stolen.

I have a GPS with a compass in it, but you have to remember to calibrate them. Really annoying.

Next up of course is that damn magnetic correction.

Confucius say, "Show respect for Grasshopper. Do not pluck off wings while
assuming he cannot fly".

That ICE 180A (and 183A) general purpose longwire matching transformer has
taps for 600 ohms and lower, and output tapped for 50 and 75 ohms, current
isolation, and some lightning protection to help protect a sensitive input.
For the simple experiments I want to do with SW listening via longwires
arranged in whatever space I can find for them, this is appropriate, it's
what it's made for. If you're plucking off wings, you're also doing it to
John Doty and a long-term maker of transformers, not just me. Sometimes it's
wiser to just assume we know what we want and help us get it. A $40 matching

transformer isn't going to break the bank or our morale if we get it wrong, and we'll learn more from trying it than from any wordplay we can do here. I also asked if anyone has John Doty's DIY plans, because he seems to know his stuff.

Here's what he says, after replying to an initial question which is included at the start here:

Would like to hear if someone has tried the Magnetic Longwire Balun by RF Systems. Does it work? Does it work as good as the manufacturer claims?

I haven't tried it, but either its manufacturers are consciously misrepresenting its capabilities or do not understand what it does. It is *not* a balun: the so-called "Magnetic Longwire Balun" (MLB) has only three terminals, while a true balun requires four.
A balun prevents net current flow between a transmission line and an antenna, while allowing energy to pass between them. With only one terminal for the "antenna", the MLB cannot possibly transfer energy from the antenna to the transmission line without also allowing a net current to flow between them.
With a proper four terminal balun connected to a proper two terminal antenna, the antenna current can flow between the antenna terminals, the transmission line current can flow between the transmission line terminals, and energy can flow through the balun without a net current flow from antenna to line.
This is not to say that the MLB is useless: except at a few resonant frequencies a wire antenna is a poor impedance match to a coaxial line. A matching transformer can significantly improve the match over a broad band. I suspect that the MLB is an effective matching transformer.
The point of using coax to feed your antenna is that it keeps currents due to noise pickup in your house separated from the signal currents picked up by the antenna. A proper balun helps enforce this separation, but the MLB not only doesn't enforce it, it subverts it. Unless the MLB is directly and effectively grounded, the second terminal of an MLB-fed antenna is the shield of the coax cable itself! Noise pickup from the house flows on the outside of the coax out to the MLB which efficiently couples it to the inside of the coax and into your receiver.
The key to getting good noise rejection from coax used to feed a longwire is grounding the coax shield well. It makes little sense to extend the coax beyond the farthest ground point from your receiver, since beyond that last ground point the coax would pick up signal anyway, despite its shielding.
Thus, a low noise coax-fed longwire will typically fall within the spectrum ranging from verticals through tilted wires and inverted L's to Beverages (long, low, horizontal wires).
You can feed this sort of antenna directly, without a matching transformer, by attaching it to the coax center conductor. The resulting antenna will show very high efficiency at wavelengths where it is an odd multiple of 1/4 wavelength long, and very low efficiency at wavelengths where it is a multiple of 1/2 wavelength long. Another disadvantage of this configuration is that it offers no protection against electrostatic damage.
A transformer at the base of the antenna can smooth out the wild efficiency swings and also give static electricity a path to ground. I've posted instructions for winding such a transformer on this group several times. If

anyone wants to see them, send me mail.
Alternatively, you could use a commercial transformer. I recommend the ICE Model 180 "Beverage/Longwire Matching Unit". Unlike the MLB folks, ICE seems to actually understand what their product does. In addition to the inherent electrostatic protection offered by the transformer, this unit also has a gas discharge tube and a blocking capacitor to further reduce the danger of electrostatic discharge. It's very solidly constructed. Finally, at $32 it's less expensive than either the Palomar ($40) or RF Systems ($60) MLB's.
ICE products can be ordered on-line at the official ICE web site Here you will find datasheets as well as free publications on grounding and beverage antennas.
The usual disclaimer: I have no interest in ICE, I'm just a satisfied customer (I have three of these transformers: thanks go to Richard Steck for alerting me to the existence of this product).

Thankyou. I think I tried both addresses.. First thing after one failed would be to try the other.. :) You might be right, could be small enough that something went wrong and stopped business for a while. I was assuming that the amount of fabrication needed to make that transformer implied a small group of people but that IS just my assumption, as one person can 'farm out' that work with a good design. I take your point about the lack of data, but as I'm after a passive device recommended by someone who knows a lot more than I do (I cited one of his messages in my other post just now, it's old

but that shouldn't invalidate it, SW listening is an old exercise, surely close to 100 years by now), and as that 180A transformer is clearly good value and low(ish) cost, I think it's a good starting base, though if I can find John Doty's plans that is also a good start.

Yech. I do some TV antenna alignments and the usual point to point
wireless. I don't bother with a compass because they're not accurate
enough. What works best is a road map, a plywood board, and some
nails. Mark your position on the map with a nail, push pin, or pin.
Mark the position of a distant mountain, building, or landmark on the
map. Eyeball the line between the two nails to the distant mountain,
building or landmark. All maps have true north marked on them. The
direction of the map arrow is true north. I can usually locate true
north to within +/- 2 degrees depending on the size of the map and the
distance to the marker. Using multiple distant points improves the
accuracy.

If you're into astronomy, sighting the north star also works well.
Also, using a computer sky chart/map to locate easy to find stars.

One I establish true north, I like to mark it on the road, sidewalk,
or deck with a line or arrow. I have a brass marker arrow nailed to
my deck.

>I have a GPS with a compass in it, but you have to remember to
>calibrate them. Really annoying.

Calibrate? You have to be moving in order for it to work. Then, it
will only tell you the direction that you're moving. If you only go a
short distance, it's not going to be very accurate.

>Next up of course is that damn magnetic correction.

I don't do no stinkin magnetic correction cause I don't use no stinkin
magnetic or fluxgate compass.

Incidentally, I have a really handy item for watching expensive birds.
I made a panorama (stitched) photo of the view from my rooftop at
home, at the office, and at my favorite astronomy meeting places. I
then marked the azimuths every 10 degrees on the JPG. Although
difficult to see the remote hilltops at night, I now have the azimuth

of anything in the sky or between me and the surrounding hills.

Thus was it always.

Well, enough here has been said, I suppose, and not enough from ICE,
the font of all blessings - a dilemma that is destined to be
unresolved without going into discussions of the evanescence of the
soul.

The "virtual" compass requires you to move since it bases direction on differential GPS readings. OK in a car, semi-OK on foot, worthless if the going is slow since the delta of distance is not significant enough to get a good calculation.

The newer GPSs have sensors in them. To null out the nearby magnetic field, you need to slow spin it around. Two revolutions generally. Or you can spin your body around and look like an idiot. The trouble is the GPS has to be level unless you have a 3-D compass. [Garmin doesn't, Magellan does. Too many complaints about Magellan gear, so you just put up with Garmin.] The GPS has a threshold where it will shift from magnetic sensor to virtual compass. You can really screw yourself up if you don't know about this.

Your technique is fine if you spot from the same location. If you are on the move, you realy do need a compass. Occasionally I'll see something off in the distance.[OK, OK, in denied access area.] Log your position, take a vector, then study it on google earth or a map. Other times I am DFing radio signals. Again, the compass does the log. Log everything in magnetic, then use your mag in magnetic, and you won't go crazy. Attempt to correct your readings and you are either correct or you just added twice the adjustment factor to your reading. Really not a good idea.

Aviation long ago decided on doing everything magnetic, probably to get around the confusion. Of course, they still use AGL (above ground level) and MSL (mean sea level) for altitude. You may recall either a Thunderbird or Blue Angel getting into trouble with this.

I use your spotting technique at times too. It depends on if I can do the preparation. Your scheme works better in mountain areas, which is where I use it since I know the various peaks and where the campsite is located.

Actually, it's not too horrible for determining the general direction
of travel. However, totally useless for determining the azimuth of
something from a fixed location.

>The newer GPSs have sensors in them. To null out the nearby magnetic

I spent some time trying to get sane readings from the fluxgate
"magnetic" compass in a borrowed Garmin GPS. The rotation method
worked quite well, until I moved. When standing next to a vehicle, it
was nearly useless.

>Your technique is fine if you spot from the same location. If you are
>on the move, you realy do need a compass.

Ummm.... orbital satellite spotting from a moving vehicle is rather
uncommon and dangerous.

>Occasionally I'll see
>something off in the distance.[OK, OK, in denied access area.]

Sigh. I suppose the alien technology that they're hiding is better
than a compass.

>Log
>your position, take a vector, then study it on google earth or a map.

>Really not a good idea.

Ok. I'll admit to having added my declination instead subtracted more
than once. Still, some additional practice and a few sanity checks
against known locations should help.

>Aviation long ago decided on doing everything magnetic, probably to
>get around the confusion.

Mostly true. All US runways are magnetic. So is the VOR. However,
all sectional maps are based on true north. GPS navigation devices
can be either way. Magnetic is a big help when using a magnetic
compass for finding the runway.

Canadian aviation is really strange. The northern half uses true
north, while the southern half uses magnetic.

<http://en.wikipedia.org/wiki/Magnetic_declination>

>Of course, they still use AGL (above ground
>level) and MSL (mean sea level) for altitude. You may recall either a
>Thunderbird or Blue Angel getting into trouble with this.

Dunno. However, I've screwed up a few HAAT calculations on FCC
license applications when I was doing them with just a calculator:
<http://en.wikipedia.org/wiki/Height_above_average_terrain>

>I use your spotting technique at times too. It depends on if I can do
>the preparation. Your scheme works better in mountain areas, which is
>where I use it since I know the various peaks and where the campsite
>is located.

It works with any decent road map. You don't even need to sight the
distant mountain peaks. Just align the map with the local roadways
and it's already better than a magnetic compass. The most difficult
part is finding a large flat area on which to place the map. When
desperate, I use corrugated box cardboard and pins for markers.

Incidentally, I have a crude system of doing TDOA (time difference of
arrival) hyperbolic RDF location on a paper map using two nails and
some string. I'm slowly scribbling a web page on the subject, so no
details until I'm done.

Oh, if you want high tech location and mapping assistance, there's GPS
augmented reality.

I love my MFJ-269.
To fully appreciate it you need to download & study the manual. It
does a lot of things other than what you read in the advertisements.

For instance: All of the coax I have is pretty old. It was top notch
foam insulated Saxton cable and I was using it for 439mhz ATV work
nearly 30 years ago. In spite of age, the MFJ-269 indicates the loss
in 40 meter service is 0.3 db. Nice to know.

Measuring inductance & capacitance is vey simple. I don't spend much
time using it because it is so quick.

Those old schemes where you quickly switch between antennas work well
for voice signals. I've found data channels don't do so well. I was
told that it has to do with how the data channels are nearly always at
full modulation. One of these days I'm going to hack two radios so
they share one local oscillator and see if I can DF based on phase
comparison of the last IF output.

The difference in distance between you and ISS and between you and STS
was 4 km. This does not mean they are 4km apart. That would only be
true if they were on a straight line from you to those objects.

A "Homer" works fine for continuous uni-directional data. It doesn't
work well for half duplex such as Wi-Fi. They're really awful for
situations where you hear multiple xmitters with the added bonus of
collisions (i.e. packet data). There are workarounds, but all require
decoding the data first and using a computah to keep track of which
xmitter you're hearing.

It will work with one big catch. You'll have to replace the IF
crystal filters with one that has a fairly stable group delay across
the IF bandwidth. If you're working with data that has modulation
components all the way to the edge of the IF filter, you're going to
go through huge variations in phase shift between the carrier and the
filter skirts. Building two matched receivers just adds to the
complexity. OAR (Ocean Applied Research, now part of Cubic) once made
an Adcock antenna DF system that had 3 receivers for measuring the
phase and displaying the direction on a scope.
<http://www.cubic.com/cda1/Prod_&_Serv/C4ISR_Prod_&_Sys/DF_Products/df_processors.html>
<http://www.cubic.com/cda1/pdf/aa1319.pdf>

Personally, I think you would do better with multiple remote receivers
and measuring the TDOA (time difference of arrival) at each receiver.
Each burst of RF is time coded and packaged along with signal
strength, GPS phase, and decoded data, and sent off to a central
computah for processing. The time codes are critical as that allows
storage, replay, and post processing. Spewing RF around Area 51 is
probably a bad idea, so post processing make sense. Collect the time
coded data on thumb drives, stuff the data into a computah on your way
out, compute, and replay the captured data later.

Drivel: If you're thinking of doing it with a Doppler ADF, then
please read my previous rants before blundering onward:

An example of British humor: I saw an old (1950s era?) British military training film clip on how to use a compass. The instructor stated that it was necessary to remove metal objects that could distort the readings from the vicinity. He proceeded to remove pocket knives, coins, pens and his belt buckle prior to reading his compass. He was standing next to a locomotive.

Just gave them (ICE) a call on their US toll-free number and they
answered immediately. The fellow said the 180A is a stock item that
can ship immediately. They don't currently take pay-pal but expect to
in the near future. He said air shipping across the pond would be
about $22 for the 1-lb package. Finally, he gave me another email
that he said should work well: iceltd@earthlink.net. (Took me way
less time to make the call than to write too many words here... ;-)

Cheers,
Tom

I fiddled with the AMOS 1090 and didn't like the big dip in the vertical axis. No amount of running the optimizer could get rid of it. I do appreciate the NEC file as it helped me understand the program.

After studying all the AMOS designs, the best plan would be to use the 3 element inverted AMOS. It is a natural 200 ohm antenna, so I assume you could skip the combiner and the associated loss. That is, just slap 4 in parallel to make 50 ohms. I'll probably be bugging you off-line on this, but I want to hack more myself er since it builds character. .-) [Of course it also wastes time, but I consider the wasted time education.] The 3 element AMOS creates a near perfect "blob" in the vertical. I could see the quad 3-element inverted AMOS working for satellite use.

Regarding TDOA, I bought two Trimble (Datum) StarLoc disciplined 10Mhz time references at Livermore. New old stock at $30 a pop. What I fool that I didn't wipe the vendor out since he had three. But at the time I didn't know if I could make it work. Anyway, I think TDOA using time stamp and synchronization via GPS disciplined clocks would make TDOA work well, even if after the fact. If I had three, I'd be TDOAing. As it stands, I was nice enough to sell one at cost to a friend, so now I need two more. I wasn't thinking TDOA at the time.

If you look at Plane Plotter, they have a MLAT for 1090. [Not every plane reports position.] The big drawback is the MLAT position reference is some other plane in the sky that is position reporting. Some airports have a constant mode-s, so I suspect there may be a FAA MLAT in the works. However, if they built the 1090 receivers with capability to use GPS timing, it would work with a simple TDOA.

<http://802.11junk.com/jeffl/antennas/AMOS-5-1090MHz/>
for the curious. Yeah, the side lobes are not going to go away with
the 5 element model. However, if you add elements, such as the 7
element model:
<http://802.11junk.com/jeffl/antennas/AMOS-7/>
the side lobes are somewhat reduced. With 40dB difference between the
major lobe and any of the side lobes, I don't think you'll have a
problem.

Hi John, I have not built one yet but am contemplating. Mine will use a Rain Bird 1" Auto Sprinkler Valve, electrically actuated (24 VAC or DC). I plan to use a Harbor Freigth 5 in one power source for the air compressor, the pressure gage, and the 24 VAC actuator supply. The power source is $60-$90 depending on the sale going on, it is also handy for lots of other stuff.

This will be my first shot because I have this available. As far as the PVC, tire valve, fishing reel, ect. don't have that much experience. As far as line, I have had one break on me after a nice launch with a sling shot. Make sure your line is of good quality. Happy launching.

No, it's not the side lobes as much as the gain dips as you sweep
elevation, i.e. starting from the horizon and going to vertical. Mode-
s is very different from your typical point to point comms. You need
coverage at all elevations. Perhaps I'm not explaining this well.
Maybe vertical plane is a better term. With mode-s, the targets are
3D. All around you, plus up and down. It is like satellite reception,
only worse since you want to cover horizon to horizon.

Think of the Lindenblad antenna, but with more gain.
http://www.amsat.org/amsat/articles/w6shp/lindy.html
The FAA has played with these, as shown in the article, but I've never
seen one at an airport. The Lindy has the advantage in that it's
circularly polarized. The mode-s transmitter is on the belly of the
bird, so you would think it's vertically polarized, but unless you
want a lot of angry passengers, you tend to fly level to the earth.
So distant plane's antenna would appear to be tilted from the
distance observer.

There are stacked Lindenblads, but I'm pretty sure that can't be done
strictly passive. There is also that variant of the J-pole that has
circular polarization, which broadcast FM sometimes uses in stacks.

All that said, my gut feeling is parallel the 3 element inverted Amos will probably do the trick. The stock antenna, which is 3dbi at the horizon, does 200nm. A receiver is at best only a few thousand above average terrain. The last time I did the math, I got a line of sight to the highest flying plane of about 330m. Using a square law relationship, that means a linear increase of about 2.7., or 4.3db. OK, make it about 7dbi.

http://yu1aw.ba-karlsruhe.de/invertamos.pdf
Figure 12 shows nearly 11db for the 3 dipole inverted amos.

That's great, thanks for that. I'll also look into a European or ideally UK source too, but that 180A was recommended by someone whose postings lead me to think they were right to do so, and unless I find better nearer to me, I'll buy it. If that thing has been a stock item for at least 14 years I think I can assume that it's right for a lot of people.

I'm still holding out for a way to reach John Doty (whose posts I read), or at least a copy of his plans for winding our own matching transformers and baluns. Got to be good to learn from those...

Lastly, I'm still wondering why Richard was so insistent on the 'grief' that comes from mentioning a stock commercial item. Surely the whole point of standardising impedance values is so that it IS reasonable to assume that a 'stock' item, chosen fopr a specific purpose, is acceptable. As this one has several choices of impedance built into it, even more so, no? Can every buyer in 14+ years also be wrong? And if so, what should they be doing instead. I've already said I also want to see John Doty's plans to understand this better. Is this also wrong? :)

The "simple" man goes away with the first 3 links ;-) ::

http://users.fulladsl.be/~spb13810/radio/swlist/ for languages, click on
an hour for tx in that hour & language

http://users.fulladsl.be/~spb13810/radio/txlist/ for stations, click on an
hour for tx in that hour & from that station

Use of the (previous and) following list: It's 3PM, where's VOA now?? Where
can I hear Spanish at 19UTC??
http://users.fulladsl.be/~spb13810/radio/timelist/ complete hourly lists
of sw tx (with crosslinks to language/ station)

The source for this data is Eibi.

I put Aoki here;:
http://users.fulladsl.be/~spb13810/radio/swlistaoki/ for languages
http://users.fulladsl.be/~spb13810/radio/txlistaoki/ for stations

Space limits made me decide to drop hourly lists for Aoki.

There are more than 700 stations, more than 300 languages, that makes about
24 hours x (300 + 700) = 24000 files on the site.

I also made a comparison of the 2 sources: aoki and eibi: (frequency order)

Source record: 11886

Dear all, I hope this is the right NG. I have an old Cushcraft AV5 vertical antenna but I can't find the radials nor the manual. I would need to know the number of radials and lenghts of them,

Thank you in advance

Here's the manual for the AV3/4/5. Radial info is on page 6.

I understand that, at one time they were docked with each other.

I bought most of the supplies last night at Home Depot. The Orbit
sprinkler valve was only about $12. It is an inline type valve like
the one in the artical. I was thinking I would use a long piece of
pipe as the accumulator but after doing the math I have decided to go
back and get a piece of 3 inch pipe to use. BTW, the cement and primer
is available in a single package for about $6.50. I am a little
concerned about the loose fit of the projectile in the 1-1/2 inch
barrel.

I will report back as I continue.

> better. Is this also wrong? :)

As one who designs all sorts of RF filters and then builds one-off
versions (if as an aid for my own bench-testing of things like
distortion in receiver circuits) or specifies parts for ones put into
production, I'd probably elect to wind my own such transformer if I
needed one, but I can certainly see the appeal of buying one.
Considering the packaging alone, it's worth it to go that way. But I
also think it's great that you're looking into postings of folk who
have words of wisdom to offer. I have the strong feeling that you're
plenty bright enough to not simply accept those postings on faith, but
will test what you learn from them against your own experiences, and

thus build your knowledge on a firm foundation.

Technical (and semi-technical) books are generally safer sources than postings, but even they are not infallible. I'm thinking here in particular about one popular book about design and winding of RF transformers on ferrite toroidal cores. You can learn a lot from the book, but it's not 100% accurate.

Best wishes for success in improving your (RF) reception -- and in learning!

Cheers,
Tom

I am sure you saw when Goggling that many use a Tennis ball with pennies stuffed inside for weigth. That is what I intend to try, will take a bit larger barrel than the one in the article. The tennis ball will cause less damage if it comes down on a car window, or someones head! Be interested to hear how yours works.

3283. MFJ-1800 2.4GHz 15dBi Yagi, again.

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-29 03:02:45 UTC
From: Jeff Liebermann <jeffl@cruzio.com>
Message-ID: <rvo3h5hhhhscg4r1vi5mm95dnma0tpp9fs@4ax.com>
Source record: 11894
Cross-posted to: rec.radio.amateur.antenna,alt.internet.wireless

I did some cleanup, error correcting, and tinkering with the model of
the MFJ-1800 2.4GHz Yagi-Uda antenna. Mostly, I tried to make the
model as close to the original antenna as possible and recovering the
macros to make it easier to tweak:
<http://802.11junk.com/jeffl/antennas/mfj1800/>
The NEC2 file is under the "main" mfj-1800.jpg page. Cut-n-paste
works.

Data sheet, of sorts:
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1800>

One remaining issue is that the stamped 2mm sheet aluminum does not
have a circular cross section suitable for easy modeling. By trial
and lots of errors, I finally settled on a diameter equal to the 2mm
thickness of the sheet metal. This is probably not correct, but does
result in the best looking gain pattern and VSWR curve.

My thanks to Richard Clark KB7QHC for help with the cross section
problem, and answering my questions.

Note that the antenna shows about a 200 ohms impedance at mid band.
That settles the debate as to whether the antenna, without the current
balun, is 50 or 200 ohms. It's 200 ohms and the 1:1 current balun is
quite inappropriate for matching or whatever. The exposed center
conductor forms a series inductance or radiator, and certainly doesn't
help. With a proper 4:1 matching xformer, the antenna seems quite
usable, but as is, it's junk. If I had one to play with (and my
HP8620c sweeper elects to cooperate), I could sweep the antenna to be
sure.

The coax is RGS-303 PTFE 50 ohms:
<http://wireandcable.thermaxcdt.com/item/high-performance-coaxial-cables/mil-c-17-coaxial-
and-twinaxial-cables/m17-111-rg303-id-70-?&seo=110>

3284. Learn the RLC circuit

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-29 03:36:06 UTC
From: brent <bulegoge@columbus.rr.com>
Message-ID: <b2eb0f9d-d73c-4d82-ba17-7c22bc36c44f@p32g2000vbi.googlegroups.com>
Source record: 11895

I have created a tutorial on the series RLC circuit. It uses
interactive flash programs with embedded audio. It is located here:

http://www.fourier-series.com/RLC-Circuit/index.html

It consists of three parts:

Program 1: The transient response of the series rlc circuit. It
includes user interaction plus all the math behind deriving the
specific transient response with initial conditions is included

Program 2: The steady state response of the rlc circuit. See how to
interpret the transfer function. Do you know how to interpret the
transfer function when it has complex numbers in it? You can learn by
seeing how negative frequency must be considered. Furthermore, you
will see not only the magnitude response of the steady state response,
but also the phase response! All math explained

Program3: See how the impulse response is derived. Use the
interactive controls to make different rlc circuits and see the
impulse response. Next use convolution to put in various input
waveforms to see the output response of the rlc circuit. You will see
how convolution actually works. The math involved in deriving the
impulse response is explained.

The pipe for the barrel is 1 1/4 in. 24 in. long. The end caps for the
projectile are 3/4 in. so there is not to much of a loose fit. I haven't
made one myself but a friend of mine has & it does just like the article
say's, use with caution & safety. I'm interested how it works with a tennis
ball, that sounds real neat. Howard K0ACF

Indeed. I make stuff from acetal and other plastics using a bandsaw and drilled and threaded holes, it's great for tough enclosures to my own design, but quickly shows how much saving can be had if I find anything that saves me a lot of construction work. The cost of that transformer can easily be recovered elsewhere.

I hope so. :) I read several. I chose John Doty's guidance for two reasons: he didn't conflict with good advice I was taught several years ago, long before I had (or built) a computer and found the net, and the other is that many good things have come out of the MIT and I think this could be in the same vein. (Sam's LaserFAQ being one of the most memorable guides).

That's certainly true... I found two commercial books on DIY laser building that were so incomplete that they amounted to little more than commercial exploiting of stuff the LaserFAQ offers for free. If I hadn't read as much as I could handle of the great amount of freely available info, I'd not have realised the extent of weakness in those two books. On my own, I'd only made a small improvement in a flashlamp circuit at schematic level but flaws glared once I learned stuff from the LaserFAQ. Another great and mighty reference tome turned out to be mostly anecdotal and frequently lacking in basic reference material, but conversely some small books written by RM

Marston turned out to be references I return to several times a year, finding them more convenient than any web-sited guidance I know. I think there's a book by Bernard Babani publishing (maybe by the man himself) on the subject of ferrite cores. Not sure if that's the one you mean but I can find it easily.

Thankyou. I'm hoping to catch a nice receiver this very day on eBay (been watching a few pass by recently), if I'm lucky enough with the price, then I'll work out what to do for an aerial..

I don't have that QST but I built one like this:
http://www.qsl.net/k5lxp/projects/Launcher/Launcher.html

I did wrap a couple of layers of electrical tape over the end caps I used.
Found some orange electrical tape that I thought would make it easier to
see..
Still sort of loose in the pipe. At 35 psi it will shoot them to about 60
feet or more. My first trial shot put it over my triband beam that is about
55 feet up. Did not mean to do that but just wanted to get the feel of how
much psi I should use. I have found 45 psi will put it over the tops of the
trees here that are over 70 feet tall.

It is a 1-1/4" X 24" barrel, the projectiles are two 3/4" end caps on
about a 4" scrap of 3/4" PVC....

Test fire at 30 PSI dry.. it huffs and honks!
Next: 35 PSI and projectile nearly straight up... disappointing!
Next: 45 PSI and leaning towards the woods. Still not too impressing.
Next: 52 PSI about 75 degrees toward the woods. Whacked the tree
smartly at bout 60 feet or so...
Next: 55 PSI a little more vertical... overshot the tree with lots of
clearance and passed over several others and rattled down in the
woods. I saw it come down but still lost it in the leaves. It is time
to get the fishing reel in place! The tire pressure gauge I measured
with may not be accurate, it is about 25 years old.

BTW: The Orbit sprinkler valve has a manual switch function that opens
the valve with a quarter twist of the solenoid. It works so well I may
not bother to use the electrical switch. With an air compressor in my
garage it will be a while before I test it with a hand pump!

I believe there are many ways to boost this thing to more power but
keeping the 3X12 tank minimizes the air requirements (pumping) and the
24" barrel is adequate to get the job done. Initial testing leads me
to believe that this device will serve my needs!

That is the model that I planned to use if the available Sprinkler
valve had that particular configuration. I was concerned about this
model because of the barrel and the tank being of equal volume. It is
good to have the testimony that it works as well! I be live it would
be easier to build and cost a little less as well. I would lean toward
the 1-1/4" barrel bore and the 3/4" tubing projectiles because I have
yet to see the 1" end caps described locally.

I may get to try a paper towel for a "patch" as used in Black powder
fire arms tomorrow. I am anxious to get up the 160 meter inverted L.

I found 12 volt DC would work my valve just fine. I used one of the
emergency battery boster packs to power mine.

It is usually beter to shoot from the woods to an open area if you can.

I found a open face spinning reel with some low test line on it. I did
not think it would be heavy enough to pull the line over the trees, but it
was for a very light line that I used to pull a heavy line back over with.

If you use hose clamps to hold the reel on with, clamp it to the air chamber
side. I found that if I used the barrel side the clamps restricted the
bore.

You do not need the projectile to be very tight.
I just used some electrical tape to make it fit beter. Used orange as I
though it might make it easier to find .

3 9V batteries in series makes a fine source to actuate a sprinkler valve. Put a 0.1 uf (or thereabouts, non critical) capacitor across the pushbutton contacts to make it last a bit longer.

3296. Faraday shields and radiation and misinterpretations

Newsgroup: rec.radio.amateur.antenna
Date: 2009-11-30 20:10:16 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <799f9609-5d11-4df8-b79a-8422406c6f15@l35g2000vba.googlegroups.com>
Source record: 11707

I have been reading the groups archives on shield antennas and Faraday shields and the different auguments regarding how shielding or the Faraday shield works. Frankly it is a total mess and should be removed so that hams are not mislead.
Shielding is very simple.
A particle with a electromagnetic field strikes the outside of the shield.
The magnetic field of same passes thru the shield some might say it is coupled to the inside of the shield.
The magnetic vector component is out of phase with the electrical field so it will be just a static particle at rest on the inside but no inline with the electrical field vector which is now a staic particle at rest on the outside
We now have a arbitrary boundary as discused by Gauss
For equilibrium all vectors impinging on the boundary must be aligned such that they cancel.
To accomplish this the inner vector or charge MUST move sideways

THE CHARGE WHEN ACCELERATED CREATES A TIME VARYING CURRENT ALONE WHILE THE OTHER FIELD VECTORS CANCEL OUT
(I believe that this was the object intended in the cross field antenna)

As with a applied varying current leaves a xmitter to create radiation, so must the receiver obtain a time varying current.

Maxwells equations show equations with the electric field, the magnetic field and a time varying current. When you have a electrical field or vector of a static particle at rest outside the boundary opposing the static vector on the inside of the boundary you have nothing left EXCEPT a time varying current in the closed circuit.
For informative descriptions of how radiation occurs view the QRZ forum of (antenna construction and design) threads (3) on the double helix
antenna (see you there)
Somebody some where should re write the above such that a definition is left for those who follow and remove the garbage which is now in place

Ok, at the risk of stirring muddy water, I'm curious now, I'm new to this group, and the subject as there clearly seems to be more to it than I knew. I also don't know of those archives mentioned so I haven't seen the context.

So in simple terms (hopefully) what is the truth of it? As far as I knew, a photon at RF with energy but no mass will produce a current that changes over time in a metal that it hits, though I imagine that as metal has resistance there must also be a voltage too. I've also heard of the 'skin effect' that means that at high RF frequencies, current flow tends to stay on the surface, so clearly the picture isn't as simple as DC and Ohm's law. I also know that when photons in optical fibres meet boundaries between layers they don't reflect simply on one side, within one region of specific refractive index, there's apparently some more complex information exchange that amounts to the photon crossing the border before returning. Which makes me suspect that equally exotic action happens when RF photons hit metal sheilds. So what IS correct? And even if there is more to it, does the aggregate of many photons, and the wave analysis of their behaviour, reduce to a simple model that makes the OP correct?

I'm asking this because calls of 'troll' and 'loony' aren't working for me.

We defiantly live in interesting times. As soon as politicians, big money
and vested interest got involved it became impossible to know the truth,
inconvenient or otherwise. I've heard here in Australia and likely it's the
same around the western world that if you wanted to improve your chances of
a government research grant, just link it some how to climate change and if
it affirmed climate change all the better.
It has always raises suspicions with me when I hear statements like all the
science is in and if you challenge us we will call you names rather than
argue the challenge.
I'm a sceptic and that includes what these so called leaked emails actually
mean!

Interesting times;
The y2k bug demonstrated the corruption of engineering.
WMDs demonstrated the corruption of the intelligence communities.
World Financial Crisis demonstrated the corruption of the financial system.
And now science!

Cheers

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

It's fairly straightforward, actually, if you believe in Faraday's law
of magnetic induction. That law says that for any closed loop
(through air, through a conductor, through anything), there is an
electromotive force (a voltage source, if you will) whose magnitude is
proportional to the rate of change of magnetic flux enclosed by the
loop. As there is no voltage drop along a perfect conductor, if your
closed loop follows the path of a perfect conductor, there is no
voltage drop around that loop, and therefore the rate of change of the
total magnetic flux enclosed by that loop must be zero. If the
perfect conductor is a closed box, then you can draw loops anywhere
through that conductor and you will never see a changing magnetic
field enclosed by that loop. Thus, the inside of the box and the
outside are magnetically independent; things happening on one side
(magnetically) are not sensed on the other side.

You can understand how this works if you realize that a changing
magnetic field outside the box that would penetrate the box if it
weren't there will induce currents in the conducting box (or even just
in a closed loop of wire). Those currents will (in a perfect
conductor) be exactly the right magnitude to cause a magnetic field

that cancels the external one everywhere inside the closed box (or the net flux enclosed by a loop of wire). An example: if you short the secondary of a mains transformer, the primary will draw lots of current at its rated voltage: it's very difficult for the primary to change the magnetic flux in the core.

Does the electric field shielding from a perfect conductor need any explanation?

Of course, an imperfect conductor will be an imperfect magnetic shield. But a perfect conductor won't let any change of field through, no matter how slow (no matter how low an EMF it generates), so a perfect conductor works as a shield all the way down to DC. A box made with an imperfect conductor is essentially a perfect shield if the box's wall thickness is at least many skin-depths thick at the frequency of interest.

That's a quick beginning. You can find lots more about this in E&M texts. There's even useful stuff about it on the web. ;-)

Cheers,
Tom

Here is a link to a generalized proof of the skin effect:

http://www.ifwtech.co.uk/g3sek/misc/skin.htm

This is exactly equivalent to Tom's explanation above. The detailed proof is quite mathematical but it is solidly based in classical physics - Faraday's Law and Ampere's theorem (both of which are embodied in Maxwell's equations). This derivation produces the well-known equations for current density as a function of depth, conductivity and permeability.

The special feature of this particular proof is that it's much more general than the ones you see in better-known textbooks - and therefore much more powerful. It shows that if RF current is flowing in/on *any* conducting surface, for *any* reason, then the skin effect will be present.

The possible reasons why RF current may be flowing can be divided into two main groups:

* "Circuit conditions" - the conductor is part of a circuit that makes RF current flow.

* "Electromagnetic induction" - the conductor is intercepting an incident electromagnetic wave which induces a current.

In either case, an RF current flows... and wherever that happens, there you will also find the skin effect.

Thanks, that helps, especially the paragraph about creating a magnetic field in response that tends to cancel the original one, and the thickness of metal with regard to frequency. The OP (Art Unwin) mentioned cancellation in more complex terms, so I'm still not clear if this validates what he said or not. It appears to but he mentions stuff I'm not likely to grasp in just an hour or two of effort.. What I'm getting at is that I'm not sure if his calling orthodoxy into question is all that drew the flak, or if there's something obviously wrong in his post that I'm missing.

Also (though I'll likely find out about this when I look deeper), why is it often ok for a Faraday cage to have holes in it? :) Braided screens, meshes, perforated metal sheets, etc, I've seen many shields that are not a complete 'seal'... UHF TV cables especially seem to be very loosely shielded but they work. Conversely, I found some nice coax in a skip once that had two heavy braids amounting to almost complete coverage around a single fine stranded core. (Found outside a telephone exchange, but I don't know what frequency they were intended for, though I used some for an outdoor VHF receiving quarter wave dipole with good results, and I suspect it will do for a SW longwire once I get a matching transformer for it).

Thanks, that linking of laws and theories will help me (and the confirmation that classical physics will be enough to describe it, as I hoped). The OP mentioned Maxwell too... so did he make some error I have yet to grasp? Other than taking pot shots at an establishment, that is... :)

That appeals to me. I think the more something can be seen to apply generally, the more it helps. Proportion can't be gauged with a model that denies it.

If it was a UK (BT) telephone exchange, then it probably was "Cable
coaxial 2003".
Used for critical video and general HF use. I don't know what it's
officially spec'd to, but it would work well up to several hundred MHz.
Characteristic impedance of 75ohms, and easily capable of 100W into a
decent match.

Sounds like the same stuff, though I have 2002 on mine (which in absence of other markings was cryptic enough that I was unsure of it, though I think it might have been earlier than 2002 when I found it. :) I thought it might be 75 ohm but I had no idea it might efficiently carry high power. But I knew it was well over-spec'd for the uses I put it to. I was lucky to find it. The staff there were happy enough for me to raid the skip, too... Should try it again sometime. That stuff seems to last forever even outside in strong daily temperature changes and direct sunlight.

I forgot to mention that I also used some for a pair of DIY scope leads for a
100 MHz scope, and they worked right even without the little capacitative
adjuster usually supplied on properly made probes. A bit clumsy, but a nice
find all the same.

If it has 2002 printed on it, that means it's "Cable coaxial 2002",
which is one down the scale in loss terms from 2003. 2002 (nothing to do
with the date!) is as good quality as 2003 (which is thicker), but the
loss is a bit higher. The three usual types were AFAIR -

2001 - single screened, foam dielectric. Quite thin - used for short
runs and jumpers.
2002 - General purpose, high quality. Solid dielectric.
2003 - Top quality (in loss terms). Solid dielectric.

All are 75ohms - like pretty well all telecom coax. (50 ohm is usually
only found in antenna feeders and traditional ethernet). The normal PVC
jacket colour was "Light straw" (yellowish cream), but other colours
were occasionally used for special purposes.

Thanks. That matches closely except the dielectric, which I think is foam (is certainly foamy or foamish). Colour is same too, though closer to white than yellow. As far as I know the impedance is purely based on the scale and geometry of the cross-section, and if so, I guess the central conductor of 2003 is also thicker. I think there were seven strands of very thin copper. If you or anyone reading this really wants to know I'll get a vernier gauge and find a bare cable end somewhere... External diameter is approx 5mm on the 2002 type.

Do you know if it's only BT internal use? If I can buy it economically, I'd consider it. I like working with it, when I'm in the mood for picking apart cable braids.

If you go back to the arbitary boundary of the Gaussian law of statics
and view it as a
Faraday shield it all becomes quite simple. If one adds a time varying
field you have the duplicate of Maxwells laws for radiation, where
the outside of the boundary is the radiator.
The Faraday shield supplies the transition from a static to a dynamic
field for xmission and
the reverse action for receiving.
Very basic my dear Watson, and a vindication that particles and not
waves create radiation
which puts it in line with deductions when other methods are applied.

You're right - my memory must be porous. 2002 has a FOAM dielectric.
Also, 2003 has a single strand inner conductor (spec must have changed -
used to be stranded). You can buy 2002 from RS - it's a BT spec, but
available for anyone. Have a look at :

http://uk.rs-online.com/web/search/searchBrowseAction.html?method=getProduct&R=5203068

It's only ï¿½58 for 100m, and the loss is reasonable at 3.61dB/100m @
4MHz. (2003 cable is 2.33dB/100m @ 4MHz)

Nice. Given what RS are charging for RG59 with a double braid that appears
similar, it looks very good. I don't know enough to choose between them
though, especially given the huge variety of cables RS show for RG59 with
costs varying more than tenfold per metre. From what I've seen of it I'd go
for that BT cable at their price. (They add VAT though..) I guess BT's
economies of large scale help this stuff to be cheaper than it otherwise
would be.

Doesn't look basic, and I suspect it never will to me. The only thing I can get from this is the idea that a particle model will do what the wave one does, which isn't surprising but I've been told that particle based models are usually best left to situations (usually atomic scale quantum mechanical) where the wave model won't do, and I've never seen anyone suggest that wave-based theories of electromagnetics were inadequate (or inefficient) for scales involving obviously large numbers of particles. The other explanations seemed to grip, but not this one. I'll leave well alone now, but if anyone else takes up the discussion, I'll read it and only comment if I can't stop myself..

This can be explained at super high frequency and at DC as easily.
However, before that it should be pointed out that the coverage (the
ratio of what is conductor to what is not - the air space) defines how
"good" the faraday shield will be. Not surprisingly, coverage is
wavelength dependant. To cut to the chase, a wide mesh will allow
increasingly higher frequencies (shorter waves) through.

Now, as to the how. With a separation in the mesh, and for very large
wavelength (in proportion to the opening size), you will have a very,
very small potential difference across any of the mesh openings. Very
little potential voltage across the mesh opening means very little
current flow around the mesh opening that is specifically due to that
potential difference.

This is not to say there isn't a very, very large current flow by
virtue of some very, very long wave. No, there's no denying that, but
to get through the mesh you have to satisfy local conditions that
demand what amounts to leakage (and this is exactly the term that
correlates to coverage when discussing coax weave). If that huge
current cannot induce a significant voltage across the mesh opening,
then the mesh opening loop current cannot induce a field through to
the other side. Now, if you examine the context of "huge current" in
a resistive conductor, then obviously a potential difference can
occur. Point is that reality (and science) allow for poor grade
shields, but as a one knock-off proof you can summon up any failure,
ignore simple contra-examples and create a new theory.

However, returning to what is well known. If you increase the
frequency applied to the mesh, then at some point wavelength will
allow a situation where the general current flowing through the whole
structure will naturally exhibit a potential difference across some
small scale. By this point, abstraction may be wearying.

Let's say you have a 10 meter-on-a-side cage with 1 meter mesh
openings. If your applied field were exciting the cage at 75MHz (4M),
then any spot on the cage could be at a very high potential difference
from any spot adjacent and 1 meter away (a simple quarterwave

relationship). This works for a solid conductor, it works for a mesh conductor.

The 1 meter mesh openings can thus exhibit a substantial potential difference across the opening, and a local current loop associated with that potential difference. The mesh opening becomes a quarterwave radiator (aka slot antenna) and can couple energy from the external field into the interior of the cage (now possibly a resonant chamber, aka RF cavity). In practice and literature, the mesh opening loop exhibits a radiation resistance of 10s of Ohms. That compared to its mesh loop Ohmic path loss, makes it a very efficient coupler of energy.

Take this very poor example of mesh, and lower the frequency to 750 KHz. The mesh opening - if we originally likened it to an antenna, we should be able to continue to do that - is now 1/400th Wave. A 1/400th wave radiator has extremely small radiation resistance. The exact value would be 751 nanoOhms. As we are examining a poor mesh, it becomes clear that it must have some resistance over that 1 meter distance (this is a real example, after all).

Being generous and constructing that cage out of rebar will give us a path resistance of, luckily, 1 milliOhm. This figure and that of the radiation resistance yield the radiation efficiency (that is, how well the exterior RF will couple into the interior) which reduces to 0.075%. The cage works pretty well, but not perfectly (it was, after all, a poor example).

Now, repeat this with a poorer conductor, or a tighter mesh and imagine the shielding effect. The mesh has an opening radius squared-squared relationship driving down the radiation resistance compared to the linear relationship of conductance.

****

Now, expanding the topic to allow for the contribution of ALL openings in the mesh, we must again return to the physical dimension compared to the wavelength dimension. If the cage is truly large, larger than the field exciting it, then you have miniscule radiators along it, each very inefficient. However, each of those radiators is out of phase with a distant neighbor (not so with its close mesh neighbors). Those two wavelength distant mesh radiators will combine somewhere in the interior space and build a field. This is very commonly found in inter-cable cross coupling through leakage that is exhibited in very long cable trays with tightly bound lines. This doesn't improve the efficiency, but sensitive circuits running parallel to power drives can prove to be a poor combination. What to do when conditions condemn the small signal coax to live in proximity to the large signal supply?

This introduces the foil shield. The foil shield is a very poor conductor over any significant length, but over the span between mesh

openings (e.g. coax shield weave), the resistance is sufficiently low
to close the conductance gap.

Well I didn't tell all in the first place because so much untruths are
buried in people"s mind.
When the charge or particle hits the outside of the shield both the
electric and magnetic fields dissapate leaving just the static
particle adheared to the outside. Ofcourse non bound particles in the
air are immediatly attracted to the inside of the shield and move
along the inside of the shield to align themselves with the outside
static particles for equilibrium.
Now for the important stuff that will upset hams. The internal
particle moves to align itself with the outside particle. By moving it
generates a time varying current such that the electric and magnetic
fields that disapated on the outside are now REGENERATED on the
inside.
Most people see or think that the outside magnetic field can pierce
the shield, which is why the name magnetic loop came about. Fields do
NOT penetrate a Faraday shield. A electromagnetic shield is
regenerated by the newly formed internal current which then closes the

circuit.
To put this with the original explanation would be to much for hams to
digest so it is best to split it into two parts.

Your statement on your web page 'It is temporarily reproduced here, under
provisions of the Berne Copyright Convention, to support technical
discussions on the rec.radio.amateur.antenna newsgroup' looks interesting
because, to the best of my knowledge, the issue of the legality of copying
parts of others' published work onto Web sites hasn't been resolved. I
can't find any specific provision in the Berne Convention that _allows_
re-publishing on the Internet - it looks more likely to inhibit it because
Web sites are automatically worldwide.

On the page 'http://www.copyrightservice.co.uk/copyright/p09_fair_use' it
is stated: 'Under fair use rules, it may be possible to use quotations or
excerpts, where the work has been made available to the public, (i.e.
published). Provided that:
a.. The use is deemed acceptable under the terms of fair dealing.
b.. That the quoted material is justified, and no more than is necessary
is included.
c.. That the source of the quoted material is mentioned, along with the
name of the author.'
But also: 'The actual specifics of what is acceptable will be governed by
national laws, and although broadly similar, actual provision will vary from
country to country.'

Presumably you have researched this matter, and I for one would be
interested to hear what you've found that appears to cover international www

re-publishing.

Chris

Yep, that's about right. In fact, my advice if you do get into that
situation (where quantization of energy is important), is to NOT think
of particles or waves, but realize that quanta of electromagnetic
radiation behave exactly as they behave, which is neither exactly like
waves nor exactly like particles. One of Richard Feynman's physics
lectures covered what I think is a lovely example of this: how you
can NOT explain the results of the experiment he sets up, using EITHER
wave OR particle behaviour. I highly recommend it, to arm yourself
against people who get into the particle-vs-wave battle. I believe
it's the sixth of what has been published as Feynman's "Six Easy
Pieces."

Cheers,
Tom

Consider that man's most ancient exposure to waves was
sea/ocean waves which, incidentally, consist of H2O
molecule particles.

Seems to me that everything that physically exists must
exist as a particle.

When you feed a time varying current to the mesh it is best to view it
in small parts, say a square in the mesh. The hole is a static field
alongside the applied current flows. This same current generates a
displacement current which encircles the static field as it returns
to the initial current flow. Of course this section is a microcosm of
the flow pattern of the applied varying current which is continually
flowing.
The initial current flow generates a field at right angles to its
axis. This field thus bisects the enclosed static field and
accellerates a particle thru this intersection in the same way a
particle is accelerated in a cathode ray tube. The particle that was
accellerated, by the way, came from the surface of the conducting wire
which is diamagnetic upon which particles or free electrons rest
without being absorbed into the matrix of the material upon which it
rests.The speed that the charge or particle attains is that of the
speed of light. So when Einstein gave up his search regarding the
standard model it seems rather natural that he came up with E=mc sqd
as it was obvious to him that light itself was generated by the same
particle or free electron that occupied his mind for so long and not
of waves that appeared to persist in the minds of physicists to this
very day.
Hope that helps you out
Regards
Art

Is this true of a discone? I'm under the impression the current flow
is identical whether metal rods or wire mesh is used in the antenna's
construction.

I am under the understanding that for a Faraday shield it doesn't
matter whether it is a mesh or solid. When the displacement current
flows in terms of an eddy current it produces a vortice which holds
the static field

Got a little further today. It takes too many hands to twist the
valve, fiddle with the reel and aim the device. I black vinyl taped a
micro switch to the valve assembly with ONE 9 volt battery so that I
can thumb it to launch. I also moved the open face reel back to the
valve end of the barrel and fabricated (more black tape & paperclip)
an eye to pass the line through so that line retrieval with the reel
is less awkward. Today's final test was conducted in the dark so I was
unable to see much. I launched nearly 90 degrees and it was gone for
several seconds so I expect it did well.

VK2KC emailed me with some advice. He pointed out that it is usually
better to launch from the woods to an open space. I expect that will
be the case.

It seems to me that this device consists of three components: Barrel,
Valve and accumulator. It seems that to change to launching tennis
balls would be a matter of fitting a 2-1/2" barrel. I doubt that I am
going to find that in my area but I will keep my eyes open.

Tomorrow is another day!

It's not basic, and it's not real.

Art has made up a whole new wing of physics that has only the slightest
ties to reality. It involves neutrinos leaping from diamagnetic
materials to radiate. And only diamagnetic materials can radiate,
unless he revised his theories, which he does regularly. And there are
NO waves, just particles And antennas don't work properly unless they
are a multiple of a wavelength, but it's OK to roll all that wire up in
a ball so that a 160m antenna fits in a shoebox. And then you can use
that with a teeny Dish network dish for directionality. Despite the
fact that those dishes won't work reasonably at anything less than low
GHz frequencies.

He is, to put it very plainly, nuts.

Nice explanation Richard. And I had never put together the
squared-squared relationship. That's a powerful thing to know.

I suppose this is why it ends up that a 1/10 lambda opening is
considered the rule of thumb cutoff frequency on a dish.

A discone does not exhibit any quality of shielding, so it wanders off
in that regard.

The difference between rods, number of rods, thickness of rods, and
mesh all speak to bandwidth. 2, 3, or 4 rods will not be remarkable.
16 rods will closely approximate a cone of sheet metal (as would a
grid of similar spacing). The same can be said of the
rod/rods/mesh/sheet in the upper section approximating a solid disk.

Again, all these "appearances" are a strict function of wavelength to
physical length and spacing relationships.

Hi Tom,

Radiation resistance certainly plummets quickly. Look at all the
tunable loops for HF that are 1 M in size AND made on an herculean
scale. I don't think any are rated at 80M (Rr ~ 5 milliOhms), and
even less so for 160M (Rr ~ 29 microOhms). This is the principle
reason why Art's inventions are doomed to abysmal transmit performance
in that band (the shoe-box sized 160M loop).

I have two Faraday shield antennas at the moment. One of which is a
large one sitting on the ground tho sometimes I raise it a foot or so
off the ground. This is an all band antenna
which the tuner in my solid state radio handles quite well., It is
made of mesh on a aluminum frame and at the moment I have not been
able to discern any noise difference and the like say on top band. I
compare it with a smaller Faraday shield which sits in the roter atop
of my tower. The antenna on the ground is square but the one on the
tower is a hexigon aluminum frame which is approx from memory about
four or five foot long and the hex is approx 3 foot across. This
antenna I use for comparison purposes where both antennas are end fed.
The smallest radiator that I have made for top band was a 1 inch
plastic pipe by about 4 foot tall. The radiator mesh was folded over
several times and then wound in helix form on the plastic tube. This
was also end fed. I could have folded it over upon itself to make it
even smaller but I declined to pursue matters. Now one can accuse me
of making up physics, but it was the understanding of physics which
the books state is not fully understood that I followed in every step
while maintaining equilibrium of the radiator.
At the moment I am not inclined to throw away either of these antennas
as they are easily confirmed for gain using a NEC with optimizer

where, at the same time, the physics that I mention is not in agreement with this group or apparently the many plagerised books on the market today. The bottom line with the pursuit of antennas is to make them small but not electrically small. It is also desirable to make them rotatable and directive with gain.
Maximum efficiency of a radiator is determined by how its size fits within a sphere and with the Faraday apparatus the radiator is the inside of the Faraday shield which makes it very efficient. I am continuing with my findings and the antennas and will not be discarding them as a child might say when lacking the knoweledge that is achieved by growing into an adult
they attain a modicom of logic that they can some meaning to their outburst
The antenna info is all on my page unwin antennas so that amateurs can join me in the joys of antenna design. As for the couch potatoes they can wave their arms as long as they want. I have also discussed it in full on qrz antennas if one wants to delve more into the physics.
Nobody over the years I have explained my findings has ever applied existing classical physics to disprove my findings providing only the crying of a child with no physics
substantiation applied.

3334. Slinkey Antenna

Hi Clyde,

That sounds like plenty of antenna for most SWLing - there's just not
enough sunspots to hook it too. A new radio won't fix that.

To those who are counting those sunspots (the missing ones), they have
theories about that which also involve the freemasons, ancient
astronauts, and other influences that will converge on a solution in
2012. The short explanation is that "time will tell."

Sorry if my post is as silly as it appears it might be, but just in case it
isn't... I've seen people walking dogs in a large park I run in a lot. They
have these slingshot/stick type affairs to throw tennis balls with for fast
strong dogs to get a lot of exercise fetching them while the owner has an
easier time of it. I've never tried one, but from what I've seen, even
unconscious practise seems to result in some accuracy, and distance certainly
isn't lacking. In short, it might be easier, cheaper and faster to practise
with one of those than to devise a more complex launcher. It seems to me that
accurately placing a thin line over a branch up to 100 ft high might be

easier than learning to fly-cast.

Another thing I remember, on a smaller scale by far, is a small stick and two rubber bands, one binding the other over the end of the stick. I was about 6, at a strange house competing with another boy to accurately and strongly catapult nasturtium seeds by releasing them against the stick so the band drew them near-parallel to it at speed. It's very effective because it eases aiming and the recoil is just enough to cause the stick end to slew aside to allow accurate clearance at the crucial instant, something that became immediately apparent at the time I 'invented' it. If the thing were scaled up, for example with a carefully prepared inner tube from a cycle tyre, then maybe the thing can launch a weighted tennis ball and light line accurately with one shot. The trial and error would certainly be a lot lower than the dog-ball-slinger. :)

A random length wire should work just fine for SWLing. If the receiver
noise increases when you hook up the antenna, then you aren't doing too
badly.

I've found that a single 9V will open a valve if there's not much
pressure, the coil is cool, etc. Run the pressure up, grab the thing
out of the back of the car where it's been cooking in the sun, etc. and
a bit more current through the coil is handy. (Oh yeah, and with 3
alkaline 9Vs, they'll last basically forever, because it will still fire
when they're almost dead... use the ones you pulled out of your smoke
alarms at home)

Don't neglect the possibility of using a slightly large barrel with a
liner (take a bigger diameter piece of plastic pipe, use a circular saw
to rip a slot down the length, and then squeeze it down to fit inside
the outer tube.

Or a sabot/piston made of closed cell foam (e.g. cut a disc of styrofoam
that fits snugly.. or I like polyethylene foam.. it's a bit springier)

Or, use one of those squishy fairly dense foam rubber balls (you see them as "stress relievers" as a giveaway at trade show booths, for instance) that are available in a variety of sizes and make a snug fit with the ID of whatever barrel you use.

In a case like that, he's doing about as well as one can do, not
counting changes in pattern. For SWL, a slinky is ok. Not so hot
for transmitting though, being the antenna is almost all loading coil
with no capacitance added at the ends. Kind of like running back
to back ham sticks with no stingers on the ends. :/
It'll work, but there are better designs for short loaded dipoles.

I am still open to all leads. I did a Google on "dog ball shooter" and
found a lot of interesting posts. I don't think any of them are up to
carrying a monofilament line over a 100 foot tree but they are still
interesting. My Black Lab enjoys chasing a genuine bowling pin when I
throw it but we are both getting too old for that game! It has given
her very strong neck muscles.

The Hyper dog launcher looks to be effective and inexpensive for the
intended purpose.

I met a fellow at Home Depot that does a lot of surf fishing in the
ocean. He is considering a similar device as my launcher to place his
bait further from the beach...

Rainy day (flood warnings) in North Carolina today... antenna play on
computer today.

It'll work, but there are better designs for short loaded dipoles.

Speaking of compromise antennas that work - at least somewhat - there is one
that MFJ has been selling for quite a while. Unfortunately, the model number
does not spring to mind, but it is for indoor use and consists of a remote
control box (remote from the "antenna") an over twenty foot run of coax and
a mobile looking telescopic element antenna on a mount of some kind (I
forget which type). It does work pretty well. A friend of mine owned one and
he lived in an apartment complex with a no external antenna rule. He did a
very good job of working out past the Mississippi on 40 meters with just 100
watts. He lived in New Jersey.

One thing I didn't catch was how often you might need to relaunch.. If lots,
then for consistency your gadget will win easily. I'd still try the inner-
tube elastic and 3 foot stick wheeze though. I also tried making bows and
arrows as a kid and was hopeless, but the straight-stick catapult really
scored.. (I'm surrounded by 4-floor buildings though so this is sort of
rhetorical, I couldn't actually do it on anything but a short trajectory to
ground here without breaking something).

That's what I kept telling myself when I first read about it 20 years ago, that light was neither wave, nor particle, but something else that can appear as either, or both. It felt like a kind of fence-sitting tautology at the time, but it really seemed the only way to have any hope of resolving (sometimes foolish) paradoxes, so it's gratifying to know that Feynman says it too. I don't know if he's written anything a layman can easily work through, that doesn't come with lots of maths without which accompanying text doesn't help much, but if he has I'll try to read it.

I have various thoughts of my own, too off-topic to go into most likely, but I'll indulge in one of them. The duality/exclusion, etc is often expressed in various ways, but the one I find most intersting is based not in massenergy but information, that of isolation and continuity. People have made computers of both types now, basically the Turing machine and the operational amplifier. I suspect we have a third type, the brain, that isn't 'modelled' on either type but uses the quanta as they actually are. Though whether attempts to make actual quantum computers will be anything like what the brain does, I have no idea. But it seems to imply that there might be a 'conservation of information' law as there are such laws for mass and energy or mass-energy. Maybe information is more fundamental than either. If so, some very strange science is going to emerge (and I suspect it won't be quantum theory that gets us anywhere, as such, especially given the Copenhagen Interpretaion and what that implies about 'knowing', but the tools it enables us to build are another matter, I think they're going to show plenty, once we have enough new info to interpret).

As continuity as well as isolation is a fundamental aspect of whatever is 'underneath', it means I have no reason to reject a wave model of electrodynamics if it works, so I won't.

Thankyou. That IS a clear picture. I'll have to learn more to understand it well but what I can grasp fits well with things I have already observed.

Regarding the other postings today, I can see that if you're receiving a long wave signal a small system will do if the sensivity is good and the noise is low, but transmission is another matter entirely. But whatever the theories propounded might be, I guess the observations are what matters. I haven't the space or equipment to test it, but if anyone manages to transmit a lot of longwave RF from a small directional system such as Art Unwin appears to be describing, then the theory will take care of itself, eventually, but I also get the strong impression that few people, if any, have done it. As far as I know, all low frequency RF transmitting systems are large, powerful things, and not very directional.

(I wrote that yesterday but kept clear of the Send button, but it's on topic enough to go for it now.)

Yech. One of the local hams was trying to use one and had the same
fit problem. Somehow, I got involved. The first thing I did was toss
a little household flour into the launch tube so I could see if the
ball was leaking. Someone appeared up with a camcorder that would do
about slow motion. Kinda like that TV show that shows things in slow
motion. The tennis ball leaked really badly.

Time to fix the leak. I decide to make a new projectile in the shape
of a Civil War Minie Ball.
<http://en.wikipedia.org/wiki/Mini%C3%A9_ball>
The idea was to have a conical head for improved aerodynamics and an
expanding base for a good seal. Of course, friction had to be
minimal. To improve the seal, I found some close cell urethane foam.
Using a hot nichrome wire, I cut a simple cylinder that was slightly
smaller than the bore diameter, and about the length of a beer can.
Well, it was the exact size of a beer can because that was what we
were launching nearby with a propane powered canon. Anyway, I also
used the hot wire to form a somewhat conical cavity in the base. Air
pressure would expand the base outward towards the barrel wall,
forming a better gas seal. The length of the foam would keep it from
wobbling. As long as the foam was a loose fit, there would be little
added friction. I never got around to building a conical projectile
and just dumped the tennis ball on top of the foam forming a sabot.

As I recall, we got about 60 ft with 50 lbs pressure using only the
tennis ball, and about 90 ft at 50 lbs using the foam Minie Ball.
Videos of the trajectory showed that the air resistance of the tennis
ball was only a little better than if it had been dragging a
parachute. End of flight droop was severe. A better aerodynamic
shape would certainly have been a major improvement. However, I never
tried.

It would also be fairly easy to add spin stabilization, but that would
require a one piece conical projectile.

You only have to visualise a large solenoid to see that it is quite
directional.
Modeling shows in the order of 10 dbi when end fed !
If you have a helix antenna in ribbon shape form where all lumped
loads are canceled
then even Eznec should be able to do the job. No need for cross wires
for a single frequency design. A mesh made into a tube and placed on
the ground will also get the job done, no hand waving required. Put
mesh around a plastic garbage can also does the job and Menards have
the mesh for less than $20 and muriatic acis for $4.
It is just that hams cannot accept change or even small non electrical
antennas.
After all, all is known about antennas as they have been studied to
death.

Reciprocity dominates, but transmit and receive circuits are not
always reciprocal (that is, symmetric or identical). If you match at
the antenna, you don't lose signal in the loss of the transmission
line where SWR would dominate. That topic is best left to other
discussion.

In logic there is the argument called Reductio Ad Absurdum. With the
claim of a resonant small antenna being efficient there exists an
obvious example that completely disrupts this. Since the inception of
man-made RF radiation, ALL such attempts have been preceded with a
resonant coil/capacitor combination. Think of the plate load of the
conventional RF transmitter in both amateur and professional
applications for the many decades that followed Hertz' work.

This small, resonant plate load, is quite specifically designed for RF
with low in resistive loss - and yet it is miserable as a propagator
of that same RF. The physical size compared to the wavelength size
dominates that efficiency with a fourth power law. Hertz' original
design was in the VHF where his "plate tank" (so to speak) was
physically large in relation to the wavelength he successfully
transmitted to a nearby physically large receiving tank.

A perfect example of an old man or woman not willing to accept change.
For the cost of a few dollars they would not have made such fools of

themselves over the years.
I have stated many times that adding a time varying current to a Gaussian field of statics
represents Maxwells laws for radiation. The group many times over say this is foolish and stupid. I know it is not stated or confirmed in the books. When one accept that statement of mine the next deductions become obvious.
A radiator can be any size, shape or elevation as long as it is in a state of equilibrium and is in compliance with Maxwells equation for radiation.
I have opreviously shown how static particles are part and parcel how a Faraday shield works. I now have shown again how Maxwell and Gauss also state that particles are part of radiation. In addition, the particle is also part of a CRT mechanism as is the salvage sorting system when sorting aluminum cans. I have also shown how the particle achieves a straight line trajectory with spin unaffected by gravity which is also essential to radio propagation.
Yet hams still hang on to the yagi and all its atributes as being the cats whiskers.
Thus size has become everything and the volume it occupies instead of distributed loads only as long as it is in equilibrium. The particle responsible for radiation and light is very small and is the perfect example of point radiation at its best.
All it takes is a few dollars and a few hours work to make such an antenna, which allows you to stop making idiots of your selves, or a modicum of physics. Instead, you are all so sure that you find no need to get up from a couch.
As I have stated many times, all the group has done is the waving of hands with no physics attached or any explanation why it is in total conformance with antenna computer programs of the day in addition to the points I have made. With groups such as this it is no small wonder that radiation has not been fully understood for more than a century.

To extend this to Art's misinterpretation of Faraday Shields:

In the old days, breadboard design was exactly that - your rig was
built on (hammered to) a breadboard. It was open wiring with open
components. It radiated well with an antenna, and poorly without one.

However, as poorly as it radiated without an antenna, if you had a
separate receiver, you would hear yourself. This was sometimes useful
and gave us what is called "side tone."

The monitor was born.

Of course, with antennas connected, the receiver was bound to get more
than enough of that anyway and if the two were closely spaced,
feedback could drive all circuits into saturation. Not a good thing.
The Faraday shield for the transmitter was born.

It, as many can witness from simple observation, was composed of a
fine grid mesh of wire either tied to ground, or to a heavily AC/RF
filtered DC potential. As with all Faraday shields that came before
it (indeed since Faraday invented it), it completely encapsulated the
RF power source. The screen or mesh was simply a contrivance to allow
cool air to move in and hot air to move out. Modern implementations
use finned constructions and heat wicks - but this is topic drift.

With this added to the breadboard, other circuits also came to be
shielded, and generally so with the appearance of sheet metal chassis
with suitably wavelength small openings for access and heat transfer.
As the breadboard went into this RF impenetrable shell for both
receivers and transmitters (and with even more care for transceivers),
there arose a problem: What about the wires that go in and out?

Yes indeed. If those wires were not, in themselves, decoupled; then
they became radiators. The lesson to be learned was that those wires
had to be held at the same potential as the Faraday shield. This
could be accomplished by a simple connection, but with more than one
wire this leads to dead shorts between wires. Not a good thing.

The solution was to use AC/RF shorts (capacitors) to the shield from the wire and the wire could only penetrate the shield through a very small (in proportion to wavelength) opening. This was not always a good thing.

A capacitor could be good, but it exhibits a roll-off of only 6dB per octave, or 10dB per decade isolation. If your line going in and out was a DC control line, and your principle frequency was 1MHz (talking about the old days now); then you had 6 decades of separation between 1Hz and 1MHz - pretty good. If in the intervening years you pushed the technology envelope and added voice modulation and that came through the same wire; then your system shrunk to 3 decades of separation between 10,000Hz and 1MHz. This might work, sometimes it didn't.

As the years spun on, more wires penetrated that RF barrier, and they needed to not only be isolated from the RF, but each other; and often they contained very small signals that needed suitable signal to noise ratio (noise being that soup of RF that was stewing inside the shield).

Inline bypass filters were born.

The lines that penetrate a Faraday shield now appear to be more multi-stage low pass filters with repeating sections of shunt capacitors and series inductors. Their common (ground to the old brass pounder) was the shield which was RF free (as it was decoupled to a sanctioned earth ground). And lest we forget the principle penetration of that old time Faraday shield:

The coaxial transmission line was born.

By all appearances, this line satisfies the convention of a small opening through the Faraday shield. It's diameter is easily very small in relation to the wavelength of the RF power it reaches into the shield to tap. In a sense, it extends that hole in the shield to some very remote area that is far from the operating position, and then allows a wire(s) to emerge without regard for further shielding:

The antenna is born.

Funny thing, however, is that presumption of the shield of the coax being inert, un-perturbing, quiescent, invisible, benign - for that presumption is an illusion, a grand delusion. The line is very long with respect to wavelength, it is in the field of excitation that has been drawn out of the soup within the cage, and it is as much an antenna as the wire that emerged from its end. Many familiar problems rise from the ashes of this illusion. The exterior of the coaxial cable appears to the field to be a very long, grounded radiator. However, at any appreciable length (wavelength raises its familiar visage with an ironic grin), this exterior surface ceases to be the familiar DC grounding strap material, and becomes a full-fledge radiator according to its physical length vs. wavelength relationship. Not a very good thing, untill:

The transmission line choke is born.

To decouple the OUTSIDE of the coaxial line, the convention that has been observed (to widespread validation) is to either wind some sections of the line into Inductive chokes, or to add ferrites which serve the same purpose. These chokes, to be fully useful to their purpose, should be found at not only one point along the line, but at several so as to suppress (wavelength based) couplings along the line, by the line and by the field.

When the combination of all these methods are employed, then the Faraday shield does what it has done for these several hundred years while allowing the migration of RF power to a remote drive point, and without allowing that RF power to re-intrude into the shield, nor along the coaxial cable. Thus, the only evidence of RF from inside the Faraday shield is that which arrives over-the-air from the remote antenna.

Any other claim is a profanation of Faraday.

Maybe I'm confused and can't distinguish between Art's all-band mesh
antennas and his mesh Faraday shields.

I was questioning Art's statement
-quote-
When you feed a time varying current to the mesh it is best to view it
in small parts, say a square in the mesh. The hole is a static field
alongside the applied current flows.
- end quote -

The idea of examining the characteristics of a single square of mesh
seems impractical. The impact of adjacent squares should be accounted
for otherwise the single square is a loop.

Either way I've learned as current varies the fields it produces will
vary. If the fields vary they're not static. Too simplistic? What am I
missing?

>The difference between rods, number of rods, thickness of rods, and
>mesh all speak to bandwidth. 2, 3, or 4 rods will not be remarkable.
>16 rods will closely approximate a cone of sheet metal (as would a

IIUC the current flows around the cone of a discone regardless of
solid, sheet or mesh construction. This appears to be contrary to the
quote above where current flows around each individual hole in the
mesh.

>Again, all these "appearances" are a strict function of wavelength to
>physical length and spacing relationships.

I've built several discones over the years and understand these relationships. How well is subject to conjecture hi.

Further discussion about these wires allowing RF to slither through
what would ordinarily be impenetrable holes.

Those holes, whose circulating currents prohibit any coupling of
fields through them, as long as they are very small in relation to the
wavelength, can turn into free-flowing fountains of power with some
rather simple additions.

As mentioned, merely pass an insulated wire through the hole. If that
wire reaches into the interior where an RF field presents a very high
potential difference to the Faraday shield, then you have a capacitive
coupling to the exterior of the shield, through the hole, along that
wire. On the other hand, if you loop that interior wire back onto the
interior surface of the shield, AND that loop resides within the RF
field where it presents a very high magnetic component; then you have
an inductive coupling to the exterior of the shield, through the hole,
along that wire. Simply terminate the outside extension of that wire
to a suitable load, observing the conventions of matching, and remove
as much power as is practicable.

This is nothing more complex than the usual design conventions already
discussed under the coaxial transmission line considerations in the
post this derives from.

The point of this aside is to remark how easily (or difficulty) the
Faraday shield can be corrupted through indifference to first
principles.

I can understand the confusion. To return to your question above,
there is NOTHING about the discone that falls under the topic of
Faraday shield.

>I was questioning Art's statement

I discussed both the single mesh opening, and the total contribution
of all mesh openings. To respond to your last statement, yes, the
single square is a loop. A very, very inefficient coupler of energy.

>Either way I've learned as current varies the fields it produces will
>vary. If the fields vary they're not static. Too simplistic? What am I
>missing?

Static comes in two flavors. One means "not moving." The other means
high potential (which can be "not moving" AND, ironically, "moving").
Such is the legacy of electrostatic potential covering DC to Gamma.

>>The difference between rods, number of rods, thickness of rods, and

Well, language can be a barrier here when you say "around the cone."

Go to:
http://www.antenna-theory.com/antennas/aperture/slot.php
I don't endorse this page, but it gives you a beginning for slot antennas and especially the construction mimicry between them and a dipole. Note in figure two that a "source" appears across the two. In the case of the slot antenna, this source would give rise to a circulating current. If you were to approach this with knowing the current alone, it would follow that the source is "apparent." In other words, the two models (or experiences) are equivalent.

Do not confuse this circulating current with a larger, general current UNLESS that more general one can spawn the circulating one. I wrote to this already and to put it shortly, it is physical length vs. wave length dependant.

>>Again, all these "appearances" are a strict function of wavelength to
>>physical length and spacing relationships.
>>
>
>I've built several discones over the years and understand these

http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm
will illustrate how varying the flare of the skirt shifts the operating properties of the discone.

So after a degree in literature you have taken to reading up on
science.
But you have only regurgutated what you have read in a physics book.
When I introduced this group to first principles every body on this
group were apaulled.
When I stated, and it was confirmed by Dr Davis, all started waving
the hands and insulted Davis and I." What" you said "you can mix up
statics with electromechanics"? "What foolishness is being stated
here." In your posting you never mentioned any thing of that!
You and nobody in the group has presented anything that refutes what I
have stated.
All this group have agreed on is that I am promoting a new fangled
science where all is already known. Now Avitar has never stated any
sort of physics that shows that he has studied in college other than
waving his hands. Ofcourse we have the ham who got kicked out of high
school so he couldn't graduate. Not his fault I might add, just some
mis understandings why he would not go to school, and it goes on. And
then we have Richard who says, why do we need new design antennas, we
have the yagi, what more can you want?

So the group is not going to rely on physics to disprove my comments because they have found that deformation, insults and loud voices is all they have to crush my claims, and it is just not working. Have they made one? No. They know the true facts on radiation so they continue to sit on the couch and wave their hands and yell

I don't sit on a couch. I sit in an office style chair. And it
probably
should be replaced as it tends to molest my differential after a
while.
Needs more particuls between the frame and the top particul retaining
cover. Due to the weak force of my differential constantly being
supported by these particuls, they have achieved equilibrium and
no longer want to do any useful work.

No you have not!
Every thing comes back to the initial finding that
by adding a time varying current to the arbitrary border of Gauss
which surrounds
a field of static particles provides the same conditions implied by
Maxwell's equations.
The group denies this fact possibly because the word equilibrium was
not of their understanding. Without understanding the connection
between Maxwell and Gauss
with respect to the addition of time makes to a static field ala a
dynamic field, it is impossible to procede with respect to radiation.
If one starts from the middle of the story where coupling of waves is
considered a basic physics understanding the debate leads no where.
Now I am not asking people to follow solely the path of mathematics
but of the concepts involved where the presence of particles is
present., To start from a small portion of the current flow and
thinking in terms of DC or the suggestion that time varying fields
cannot surround a static field is just ludicrous. The subject is
Classical Physics and one should keep on subject if one is to fully
understand radiation. Denial of select parts of classical physics
without supplying reason ans substituting insults instead is not going
to solve anything. And as you did not graduate from high school it is

perfectly understandable that you will find difficulties in parts of the debate and yet you would like to contribute to the debate. But insults will not get the job done.
Of course one can go back to the basics of mathematics way back in Arabic times where
the mere presence of an equal sign denotes equilibrium or balance. The equal sign is part of Maxwells equations so equilibrium is in effect. This immediatly tells you that any radiator considered must be a function of a full wavelength or a period with respect to a continuing variable sign wave. Immediately one should note that a half wave has no place in our calculations as the two areas under curve for a period can never be the same because of overshoot phenomina, thus it is the period that is repeatable and to be used. One can also deduce that a radiator must be in equilibrium to be part of the same reasoning thus resonance on its own is not part of the mathematics. There are plenty of ways to see how current thinking on antennas is certainly not inline with the equations of Maxwell, thus it is very important to start from "first "principles and not just accept the books. And that the importance of adding time to a static field enclosed by an arbitrary boundary to ensure the correct metrics will be used at the outset.
Art

I think one of the key things that made his physics lectures popular
is that they were delivered without a whole lot of math. You could
get into that if you wanted, but you could also get a lot out of just
listening to the _ideas_.

If you drop me an email, perhaps I can send you a bit more about this
particular lecture...

Cheers,
Tom

The antenna sold today as a "slinky" is not the slinky of old as shown
in Jasik's book.
If one is to put a lumped load into the schematics of an antenna then
one MUST add a cancellation to the structure as the intent for maximum
efficiency of radiation is the correct use of distributed loads only.
The present day slinky consists of continuous length of wound
inductance or a "lumped" load. The true slinky consists of equal
amounts of clockwise and clockwise turns such that the lumped
inductance is canceled leaving only distributed loads.

O.T
As far as the "soot" term being presently bandied around, it is an
adjective which describes the chemical effects of combustion. Only
those old in the tooth or unfamilier with physics describe it solely
as a product of burning coaland nothing else!
This is similar to the use of "waves" in physics with respect to
particles. One is a noun,
where the other is a adjective that describes the action of same.

That is oh so true! The masters started with an observation of an
occurence and not from
a rendering of mathematics. With more observations it became natural
to align the Universe via mathematics which, as with a jig saw puzzle,
fits together nicely.,
It would seem today that scientists today are using mathematics via a
computer to churn out bundles of equations leaving the operator to
think of an observation that would fit the math. Of course,
mathematics provide imaginary answers similar to a quadratic equation
that finish up as multiple of false leads and deductions which
eventually requires the multiple use of constants to provide a
semblance of understanding of what has been provided.

Made up physics again. Unproven by any math or demonstrable effects.
Try a new line of argument, this one gets you nowhere.

Denied by the group because it contradicts everything that is proven to
work, as well as all published and mathematically backed theories.

And provide some proof. Even just a little. Rhetoric doesn't count.

You accuse others of sitting on their asses and not building antennas
and measuring them, when you have never once done it yourself.

I have built many antennas and provided many independent performance
measurements right here. And so has almost evreyone you argue with. We
all make things and MEASURE them. You don't.

Uh Art? There are no rational concepts in your presentation, please provide some.

And there's no "math" at all in your mathematical presentations, just a bunch of bafflegab. Please provide math.

Oh, I forgot, you can't. All you can do is babble. And accuse people of foolishness in their disbelief.

I must say, you are entertaining when you don't take your medications.

And you still can't spell or put together a sentence. I would suggest a spell checker at the very least.

Bla, bla, bla, bla.. We need to get you a new needle that doesn't skip
and play the same broken record over and over again. :/
You whine and moan about my education, which BTW, you have no
idea of knowing what I have learned in the 35 years since then, but
you
stun us with such proof of your all knowing knowledge by referring to
sine waves as "sign waves"..
Chortle..
Give me a break.. Your education in things RF is probably not much
greater than mine is being as you didn't take the relevant courses
in school. It might even be less being as I have a decent library
and I don't distrust everything I read without actually testing it
first.

And I actually build and test the antennas I talk about. On the air.
In front of real people. I've got nothing to hide. When was the last
time you actually compared one of your antennas to a known
benchmark?
At at a testing range. Or on the air.. In front of real people...

I'm afraid using mumbo jumbo pseudoscience theories are not going
to propel your obviously inefficient antenna designs to greatness.
I realize this must distress you greatly, but it's a situation that
can

be dealt with with the proper medications and therapy.

Tom
Give me a clue whether you are in junior high school or have a track
record of achieving something higher. You have never enunciated or
even given a clue that you have ever taken a physics course or for
that matter any engineering course in any of your postings.
It seems like you are awful young and not yet an adult to put some
scence or logic to any thing that you say! You talk of no "rational"
in my statements, but as yet have not presented

anything to back you up. I have read thru a lot of your postings but as yet have not come across anything from which I can gauge some of your knowledge and expertise with respect to antennas and radiation. I have gathered that you have had some experience in installing consumer dishes and I recall you stating that dishes can only be used in the giga hertz range, without mention that it is the size of the antenna determines whether a dish orreflecter is pertinant or not. Very strange!
Because of lack of comment from others one can assume that they know you better than I do and are content with a glance in the air with a sigh and maybe I should follow like wise. I read your post again and note that you want the math. If I gave you a starter with respect to Gauss and Maxwell would you give me a hint with respect to your present understandings with mathematics. Lets face it, you never proved the mathematics wrong when it was presented to you by the good doctor where every body also denied its correctness, so it is awfully difficult to proceed when you deny the feasability of the initiating statement. If it makes you feel good then continue with your insults in leu of not knowing anything else to say.

"the mere presence of an equal sign denotes equilibrium or balance"

So sayeth the master of the physical universe - Art Unwin...

Hmmm, so if there is an equal sign, it means it's in equilibrium.

So a half wave antenna = 468/f(Mhz).

It is therefore in equilibrium.

Dishes are usable based upon their size relative to the frequency of
use. You seem not to understand that.

They work by reflecting the EM waves directed at them. The gain is set
by the area of the dish in square wavelengths, and your pretend physics
can't change that.

A DSS dish isn't even a pinpoint to reflect off of at 160m, which is
your favorite example.

A dish that provides only 3dB gain at 160m would be approximately a
kilometer in diameter. How big is your mom's garden?

So stupid. A half wave does not have a measurement that is repeatable
therefore it is not in equilibrium. The point of repeatability is a
"period". Surely you learned that in Jnr High!

Again how foolish you are. There are many radiators that have
reflectors that are way below the GIGA Hz level. You are basing your
statement on laws applicable to planar forms of radiators.
Heck! There are many helix antennas in use that have reflectors that
are used in the Mega Hz range. There is absolutely no good reason why
a antenna for top band must have a reflector a kilometer in diameter
if the antenna itself replicates a point source.
I think you have shown everybody the extent of your limitations with
respect to antennas!

That's correct. The equal sign denotes the presence of balance. Making up an equation that is not in balance is not corrected by the addition of an equal sign. Starting with fraud in mind never can later be corrected other than the continuance of fraud. Seems like your efforts in persuading others of your expertise is not working out as you thought.Just the opposite.

A typical helical antenna would be in the "mega" hertz range would be for 435 MHz. The planar reflector for that antenna is 70cm, or 1 wavelength. Which would lead one to conclude that a planar reflector for top band would be about 160m.

And now Art will make up more new physics for his response.

Electrostatic is properly applied to charge that is NOT moving, or
moving very slowly.

The same thing can be said of Magnetostatics as being derived from a
current that is constant, or altering very slowly.

The sense of either of these strict terms residing in the RF denotes
the poverty of idea that takes up residence here as invention. There
is plenty of examples to be found on the Web too. It is unfortunate,
like the camel's nose under the Arab's tent, that taking "very slowly"
and winding out the tach to 100GHz is the pollution of meaning.

What we are concerned here with is electromagnetics infrequently known
as electrodynamics and rarely as magnetodynamics. The sense behind
electromagnetics is inclusive of dynamics of which statics is a
special case.

Dynamics, of course, means time-varying. In EMF, or electromagnetics,
what varies is magnitude and/or polarity of the electric and magnetic
field. What you find "constant" about the fields (properly observed
as plural) is in their orthogonality (one field is building the other
as it decays in amplitude).

>>Well, language can be a barrier here when you say "around the cone."
>>
>I should have said the current flows around the cone parallel to its

Could be very damaging. When I lived in Minnesota on top of a hill I
ran some 4AWG wire from all the metal vents and anything metal down to a
fence post steel stake I had driven into the ground. 2 months later we
got hit by a big strike and the whole house shook but there was no
damage except that the wire on the fence post was welded by the hit.
Must have been big to instantly weld 4AWG into a stake post.
Without the wire, who knows?

WTF? That was one of my favorite stores to hang out and spend $$$ when I
lived down there. What happened? They always seemed to be thriving and
had books on other subjects. Fry's simply never had the books to compete.

I think I have a good one for this thread. Get about 500 feet of 24 to 28 AWG magnet wire and wind it onto a fishing pole that has the easy cast and not an ocean reel. Put on a fair sized weight and then cast over the first tree in sight. Have someone walk around and find the weight on the ground and throw it over the next tree. Do this until the wire is used up or there are no more usable trees. I am going to try it on my next outing.

Bill Baka SWL only.

This could either get very confusing, or very revealing, not sure which yet. I found that no terms I knew fitted that well so I ended up using 'flux' and 'stasis' NOT to be confused with motion and stillness. By which I mean motion and stillness are the phenomenon, but flux and stasis are what lies beyond, in a pattern of information for want of better expression. To illustrate, a tap turned to release a flow of water often shows a stationary pattern while water is obviously flowing. That pattern is a stasis, but the water is not still. I don't know how useful this is when resolving a distinction between kinetics and dynamics, but it does look like we have to be careful about how we use these terms or we might not know which we're talking about, the standing pattern, or a manifest stillness. If we can't be clear on it we might as well be trying to pin down the 'evanescence of soul'. (Richard Clark, that was a good one, it's right up there with the better phrases from Douglas Adams.)

If I recall correctly, they were bought up by another company (or, at
least, changed names) and then finally closed.

I don't know what the economics of their close-down were. I suspect a
combination of factors: rising rents (things were getting a big crazy
during the dot-com bubble), competition from online book-sellers such
as Amazon, increasing cost of purchasing inventory, and increasing
cost of maintaining stock (business taxes on unsold inventory).

>Is there anything in the Sacramento area or even the Silicon Valley area
>anymore?

There's another technical bookstore called Digital Guru, located in
the next strip-mall section northwards from where Computer Literacy
used to be. They don't carry as broad a stock as CL did, but they
aren't bad.

These days, I tend to look on-line first.

Douglas Adams is good, but I have just discovered Arnold Bennett's
"BURIED ALIVE
A Tale of These Days"

...over a narrow doorway, he perceived the image of a green tree, and
the words, 'The Elm Tree.' It was the entrance to the Elm Tree Tea
Rooms, so well spoken of in the Telegraph. In certain ways he was a
man of advanced and humane ideas, and the thought of delicately
nurtured needy gentlewomen bravely battling with the world instead of
starving as they used to starve in the past, appealed to his chivalry.
He determined to assist them by taking tea in the advertised
drawing-room. Gathering together his courage, he penetrated into a
corridor lighted by pink electricity, and then up pink stairs. A pink
door stopped him at last. It might have hid mysterious and
questionable things, but it said laconically 'Push,' and he
courageously pushed... He was in a kind of boudoir thickly populated
with tables and chairs. The swift transmigration from the blatant
street to a drawing-room had a startling effect on him: it caused him
to whip off his hat as though his hat had been red hot. Except for two
tall elegant creatures who stood together at the other end of the
boudoir, the chairs and tables had the place to themselves. He was
about to stammer an excuse and fly, when one of the gentlewomen turned
her eye on him for a moment, and so he sat down. The gentlewomen then
resumed their conversation. He glanced cautiously about him.
Elm-trees, firmly rooted in a border of Indian matting, grew round all
the walls in exotic profusion, and their topmost branches splashed
over on to the ceiling. A card on the trunk of a tree, announcing

curtly, "Dogs not allowed," seemed to enhearten him. After a pause one of the gentlewomen swam haughtily towards him and looked him between the eyes. She spoke no word, but her firm, austere glance said:

"Now, out with it, and see you behave yourself!"

He had been ready to smile chivalrously. But the smile was put to sudden death.

"Some tea, please," he said faintly, and his intimidated tone said, "If it isn't troubling you too much."

"What do you want with it?" asked the gentlewoman abruptly, and as he was plainly at a loss she added, "Crumpets or tea-cake?"

"Tea-cake," he replied, though he hated tea-cake. But he was afraid.

"You've escaped this time," said the drapery of her muslins as she swam from his sight. "But no nonsense while I'm away!"

****

I have included this vignette simply to fulfill Art's fulmination against all things English (the author to this vignette) and literary. Most readers are already aware that Art would spit on Shakespeare, drowning him, if there stood any chance of that getting me damp. ;-)

I once encounter a young wag on campus (a LaRoucheitte in disguise)
trying to argue (there seemed to be no other outcome expected to this
encounter) that Pythagoras law was wrong.

The hidden agenda seemed (and I say seemed only because this disguised
follower of LaRouche could never get to the point) to be for (or it
could have as easily been against) Nuclear power.

He waved his hands at the sun as the font of all energy (what this had
to do with Pythagorean law was a long and rambling exercise) and that
oil was for naught in comparison. I harkened to comparisons as they
are often fraught with error... my argumentative dwarf snapped on that
hook like an intellectual turtle.

He invoked how much power there was to be had by turning the moon into
our own special sun by nuking it. I venture to offer that we needn't
send missiles to the moon when a match head had enough ooomph to power
Seattle for a day. (I drew my own comparison carefully, knowing the
rhetorical advantage of choice in a match.)

"How could a match head barely light a cigarette, much less power a
city for a day?" Came his indignant, and proud retort - thinly
disguised as the master-stroke of logical humiliation.

I pointed out the difference between nuclear energy (his topic of
choice) and chemical energy (his topic of complete equal ignorance),
two concepts his arguments wandered between without care nor concern
for accuracy in terminology or science.

It was just my luck that all this attracted another eavesdropper who
wanted to dip his oar in this polluted water. I stepped out quickly
with my disguised LaRoucheitte chasing me with epithets such as "I
hope I'm never in YOUR class!"

Well I still like my idea of flux and stasis but that aside (it's never really been practical, just helpful when trying to understand some things), that writing has topspin, it carries. I might try it. I was disappointed by Terry Pratchett, but this one looks as new as Adam's stuff did when it was new.

Btw, I think I worked out how Adams came up with the Long Dark Teatime Of The Soul, as a name, and some meaning behind it. I like myeteries so all I'll say is I think it emerges from a bit of French classical music....

After today's experience I think I can see a problem coming for you.
I was ready to move to the second tree today. After a couple of false
starts (valve leaking around pipe threads & add the second battery per
advice) I popped the line over the intended tree plus two more. The
line ran out smoothly but stopped with a jerk. I ran out of line on
the reel! The projectile was hanging about 30 feet from the ground.
After much fussing around I managed to reel in enough line get to the
top of the intended tree. It seems to be best to reel the line in very
slowly because the projectile tends to flip around the limbs and wrap
itself tightly. That is what happened to today's effort. The
projectile is tightly jammed at about 65 feet up the tree with a good
portion of the available line out of reach. I took the XYL to dinner
and stopped by WalMart for more line for tomorrow...

What I am getting to is that you will need a plan for what to do when
you pitch the weight in the tree and it don't come down!

100% chance of precipitation tomorrow afternoon (may be even snow) in
the North Carolina Piedmont. Great antenna weather!

You probably should have just cut the line off the reel and let the weight
drop. When I miss, I cut the weight off and reel it back in, then reattach
the weight. As mentioned, the weight will tend to wrap around places where
it is not wanted.

Looks like a radio day for me to John as I am just down the road near Salisbury.

Strange! So many things make me think of a certain style that goes with the time, that feels old, the kind of thing that pervades early science fiction or romance or Victoriana in general. That extract had a drive a clarity that could easily be taken for something post-William-Gibson but without the obvious futuristic affectations. My dad was born 100 years ago, so I will read this stuff, it might give a useful perspective on how people saw their times, instead of how we have been so often made to see them.

(And if anyone can find anything to do with antennas here now I admire their skill :)

No, no, the snags are going to win. :) Friction can be a vicious mistress.
Which might mean that very cold wet conditions favour the business, as it
happens...

One thought... how acccurate is this launcher? Any chance it can be aimed to
hit the branch above target and bounce to assist further directed travel?
(Sadly I wouldn't trust my stick and elastic trick with that move).

Art has made claims for discovering antennas that were commonplace for
Bellini and Tosi who he refuses to acknowledge predating his
"theories" 102 years ago.
http://www.astrosol.ch/thisandthat/5379039a840e79e07/index.html

And, as you are such a willing prospect for situational humour (as
just such as we indulge here anyway without regard for literary nor
scientific merit); I push the envelope by enlarging upon parallels to
Art - both literal and figurative (as evidenced by the last line):

This unique seat was occupied by the principal player, who wore a
humorous wig and a brilliant and expensive scarlet costume. He was a
fairly able judge, but he had mistaken his vocation; his rare talent
for making third-rate jokes would have brought him a fortune in the
world of musical comedy. His salary was a hundred a week; better
comedians have earned less. On the present occasion he was in the
midst of a double row of fashionable hats, and beneath the hats were
the faces of fourteen feminine relatives and acquaintances. These hats
performed the function of 'dressing' the house. The principal player
endeavoured to behave as though under the illusion that he was alone
in his glory, but he failed.

There were four other leading actors: Mr. Pennington, K.C., and Mr.
Vodrey, K.C., engaged by the plaintiff, and Mr. Cass, K.C., and Mr.
Crepitude, K.C., engaged by the defendant. These artistes were the
stars of their profession, nominally less glittering, but really far
more glittering than the player in scarlet. Their wigs were of
inferior quality to his, and their costumes shabby, but they did not
mind, for whereas he got a hundred a week, they each got a hundred a
day. Three junior performers received ten guineas a day apiece: one of
them held a watching brief for the Dean and Chapter of the Abbey, who,
being members of a Christian fraternity, were pained and horrified by
the defendants' implication that they had given interment to a valet,
and who were determined to resist exhumation at all hazards. The
supers in the drama, whose business it was to whisper to each other
and to the players, consisted of solicitors, solicitors' clerks, and
experts; their combined emoluments worked out at the rate of a hundred
and fifty pounds a day. Twelve excellent men in the jury-box received
between them about as much as would have kept a K.C. alive for five
minutes. The total expenses of production thus amounted to something

like six or seven hundred pounds a day. The preliminary expenses had run into several thousands. The enterprise could have been made remunerative by hiring for it Convent Garden Theatre and selling stalls as for Tettrazzini and Caruso, but in the absurd auditorium chosen, crammed though it was to the perilous doors, the loss was necessarily terrific. Fortunately the affair was subsidized; not merely by the State, but also by those two wealthy capitalists, Whitney C. Witt and Mr. Oxford; and therefore the management were in a position to ignore paltry financial considerations and to practise art for art's sake.

Should be kinematics (not kinetcs): "Branch of physics concerned with the
geometrically possible motion of a body or system of bodies, without
consideration of the forces involved. It describes the spatial position of
bodies or systems, their velocities, and their acceleration".

The kinematics describes motions without consideration what and why.
>
> This could either get very confusing, or very revealing, not sure which

EM is the first step. No the next for the incompressible fluid. The electron
were discovered and the dynamics are done for them.

> Douglas Adams.)

For flows are also the flow kinematics and the flow dynamics.
"An accurate theory of electromagnetism, known as classical
electromagnetism, was developed by various physicists over the course of the
19th century, culminating in the work of James Clerk Maxwell, who unified

the preceding developments into a single theory and discovered the electromagnetic nature of light. In classical electromagnetism, the electromagnetic field obeys a set of equations known as Maxwell's equations, and the electromagnetic force is given by the Lorentz force law. "

It seams that EM is the field kinematics.

I am not familiar with Arthur Daley, but your close editing has very
much converged on the psychology of this side-topic. We have with us
now a late-coming ankle bighter kinetically trying to compete for that
humorous wig.

However, that aside and in fitting to the context of the group, I
offered a link to an equally old reference of Bellini and Tosi that
should be very interesting to you, as a SWLer. If you revisit that
reference, then take note of the goniometer where its receive
application would allow you to perform your own crude beam steering
using two orthogonal long wire antennas (or crossed dipoles).

Daley's great, well worth trying to see. (Minder, TV shows circa 1979 or so).
The books aren't high literature but they are good (written by Anthony
Masters) and do offer something beyond the shows, and they stand some repeat
reading too. I think Wodehouse is better and funnier, but Minder really has
its perks. Cheerful Charlie Chisolm, for example... Best detective since
Clouseau.

I need to install a few of the old style Motorola connectors to use with some equipment that uses them. Just wondering if anybody knows the proper way to do them. I assume you just solder the center through the tip... But I'm not quite sure what the proper thing to do with the braid is.

Thanks for any help.

Rents I believe. Even in this depression people are trying to raise the
rents. I know from experience owning a TV/electronics repair shop. At
exactly 1 year the girl representing the landlord told me that since we
were a success and made it a full year they were going to raise my rent.
My answer, "Sorry, greed doesn't get it, I'm closing.".
That was easy because business sucked except for the truckers and my CB
tuning skills at 5:00 A.M.

I have a big reel of magnet wire about 22 or 24 AWG, meaning probably
miles of it, so I can lose some. A lead weight is disposable so I won't
cry over it. I may leave some of these antennas at favorite spots for
future use. A fishing rod just casts really far for me so it is my
weapon of choice.

at least it is a civil discourse and the material is at least well
grounded in basic facts as opposed to the way the thread started.

Too many non-precse variables for accuracy. Air pressure, temperature,
elastic accumulator, projectile geometry and line drag.

The book what you read lied to you!
When you look at a sinosoidal curve the area above and below the datum
line is never equal ! If it were you have invented perpetual motion.
Power is continually being injected to make up for frictional
losses incurred. After a full cycle you get to what is a repeatable
point termed as a period where you have adjusted the energy contained
to equal that of the beginning. With the areas not being equal because
of frictional losses the curve crosses the datum line at a point not
at the half way point of a period. This point is resistive, where as.
if you put it next to the true half way point you would see that the
points were not one and the same. This sequence of events is that of a
"tank circuit"
which you would learn about if you went to college!
Resonance is the point where the curve is totally resistive only and
it does not represent a point of equilibrium. A period or a FW point
is also totally resistive and in a state of equilibrium, a point of
repeatablity which the half wave point does not
When dealing with the laws of Maxwell, which includes an equal sign,
metrics used are only those that represent equilibrium which, in the
case of radiation requires multiples of a full wave (FW) where the use
of the half wave would nullify the equal sign and the whole equation
No where does Maxwell's equations suggests a particular shape or
elevation or even straght when describing a radiator, only that it is
at a state of equilibrium. Thus a radiator can conform to Maxwell's

equations when totally compressed to a point source which certanly would not require a reflector representing a straight length of the magnitude you have stated.
Note also that Maxwells equations refer to distributed loads only and not lumped loads which, if present, MUST therefore be canceled.
Art Unwin KB9MZ....xg (uk)
Hopefully you are now back on track with respect to the science of radiation.

IIRC, he had the design posted on his webpage and perhaps in QEX. I don't
remember him ever giving details to QST or to this group, but he did
eventually provide construction details on a "fractal vertical". Brings
back memories of spirited discussions. :)

Kosmas,
The given diagram shows the number of turns and diameter of the
matching coil. I'm not sure that the exact spacing is going to make a
huge difference. And as long as it's at least 'close' to what's
shown, should take no more than the 'normal' amount of tuning.
Good luck.

Maxwell dealt only with the mathematics of the time where many people had arrived at equations with respect to scientific observations. Many of these equations from different countries were actually duplicates so he was able to side line some. reduce some and even combined some such that he has a set of equations. Ofcourse he was aware that with observations within the Universe one must obey the requirement of equilibrium. You can do this by placing all metrics on one side of the equal or equal ibrium side and zero ion the other side.
One of his final equations did not, in fact, equal zero and in fact the metric of time was missing among other things. Now he couldn't go back to Gauss or anybody for an explanation. If he had spoken to Gauss he may have told him that if he made a static field dynamic he could correct the initial equations provided as the product was one and the same! Instead Maxwell concerned himself only with the metrics of the equations and not the scale. So he cancelled the metrics that were available and then added some metrics so he could cancel what was remaining which implied equil ibrium noy knowing what the additions added signified. At that time he could not have cared less as he primarily a mathematician.
When Yagi and Uda came along they stumbled on intercoupling of planar forms with out any regard to Maxwells equations. For them, the use of half wave length was of no concern as it provided answers that were within 10% of real life. That aproach lasted to this very day when I came along and pointed out that by using the Gaussian law of statics

they could then account for the remaining 10% of radiation by accounting for other forces which could provide for 100% efficiency. When this observation was shared on the internet it met with disdain by those who in the absence of knoweledge followed the trend of the written books of science known for their plagarisms. After all, those who followed the books to the letter were resting on the mantle of perceived experts where all agreed on the same thing. Rather than learning new things about physics they decided to agree to bestow on the teacher the myth that he was wearing no clothes and threw away all the mesh available . To this day nobody can apply a time varying field and note that it radiated more efficiently than any radiater known and occupy a smaller volume than previously .possible thus preventing those with small gardens become such loud mouths as others were that were preventing the advance of science.
Now the antenna industry realizes that with the gaussian knowledge being denied to them the only resort they had for advancement was to invent a new technology so they could carry the battle to those who cannot accept change. Unfortunately God made only one technology for radiation leaving the industry to ponder for another 100 years.

Hello John,

In my opinion pneumatic systems can have good shot to shot
performance. When you use projectiles of about 0.1 kg width about 25mm
diameter, the required muzzle velocity is in the 25 m/s range (to
reach >70 ft). As this is far below speed of sound, mass of the gas,
hence temperature effect should be negligible.

The weight to diameter ratio assures that air friction has less then
10% influence on height and distance. Maybe you can add something to
avoid tumbling of the projectile.

When you have a large bore fast opening valve (< 10ms) you should have
good performance with relative low pressure (<50 psi). When you
experience bad repeatability, it must be the valve. If you like to
experiment further, you may construct your own piston valve that
interfaces directly with the barrel (coaxial structure).

Over here (Netherlands), law is very strict. Even pneumatic spud guns
are weapons and you may not make them as far as I know.

Good luck with the launcher!

I remember seeing a construction article, but not sure where.
I looked through my Communications Quarterlys and found summer 1995
has an article "Fractal Antennas Part 1, Introduction and the Fractal Quad"
You might be able to build an antenna from the article, I couldn't.
They sell the article here.
http://www.fractenna.com/nca_reprint.html
I don't know if part two was ever printed.
Chip took a lot of heat about this idea, probably would have
saved himself a lot of grief if he would have skipped the whole ham thing
and just started marketing them as shrunken antennas.
Mike

No he isn't a buffoon, he had a Doctorate! Yes this group did go after
him with insults e.t.c. until he finally left and went into business
leaving the group devoid of experts again. He has several law suits
filed against the biggest phone makers in the world where they were
using his ideas with out his knowlege and not paying for them.If it
is found that he is correct that other phone makers felt they had to
use his ideas to stay in business then it would appear the ideas had
merit.
He wasn't the last antenna expert to leave the insults from this
group,
Tom W8ti was one , Litchfield is another who left, Llewellen rarely
appears now and there were a lot more that left. The pseudo experts
are still here and easily recognisable and there are many a day that
the newbies will not come near this newsgroup to ask a question. No,
Chip was not a buffoon and is laughing all the way to the bank despite
criticism from those from those who decided there was no need to go
to college or even high school because they could holler louder than
anybody else and win.

I found a Comm Quarterly index, Chip has more Fractal articles.
summer 1995, spring 1996, summer 1996 and winter 1996.
I dont know if any are construction articles.

> Art Unwin KB9MZ.....xg

Ofcourse the biggest thing to come from the Gaussian observation was
that his static particles must be in equilibrium and also could only
come to rest without harm was a diamagnetic material which could
encapsulate vie their density. Most other things on earth are
considered diamagnetic including water. Many people have seen beads of
water that can exist in a pherical shape as you see with mercury and
the like. This is because the liquid is bound so tight by the resting
particles that they assume the shape of a sphere where internal
pressure equates to the outside pressure. When the winds pick up
particles are drawn up while clinging to the water where the surface
area of water diminishes with altitude The resting electrons or
particles receive a charge via the assending movement while at the
same time struggle to look for a viable new resting place such as a
close by cloud while all the time gathering increased charge. These
electrons collect in a cloud like form themselves as points of rest
diminish such they are attracted away from the higher elevation back
to earth which is now the easiest place to reach and rest. Thus we
have lightning produced when the cloud of electrons hit the ground
such that the charge removes itself from the charge.
You might also notice that the radiation resistance increases as the
metallic resistance decreases. This is due to the encapsulating
electrons carry more and more of the current available such that the
skin depth starts to disapear such that we have to review what the
lowest impedance that can be handled for radiatiation. The action that
removes the encapsulating particles is both a directive force and one

of spin. These same two forces are responsible for all actions on earth such as gravity associated with spin all the way back to the big bang where equilibrium is broken via a emerging particle from the suns boundary. So what was originall thought of as being a wave is now seen as a total error as the particle is the initial subject of force together with spin which thus brings to the fore the formation of voltage, light magnetism and even gravity byt he adherance to Newtons law that require s from every action an equal and opposite reaction which travels thru the Universe by the single ejection of a particle creating the two basic forces from which everything comes about. Even the Faraday shield follows the same pattern where the field outside equals the field inside until the internal or external equilibrium is broken creating the same two originating forces of the universe. Now if I made all that up myself wouldn't one think of me as a visionary that really should write a physics book to steer the world in the right direction of fictional law?
Had a great long week end in StLouis which has revitalised me back home in Central Illinois to with stand the new oncomming insults who feel that they know all about antennas before I was born.

3442. Seeking New FAQ/Intro Maintainers for rec.radio.amateur.*

Newsgroup: rec.radio.amateur.antenna
Date: 2009-12-07 07:05:00 UTC

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:
```

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

What those patents cost to get would make a handsome annual salary.
Especially if any were initially rejected.

The problem is with Google. When I went to Yahoo and pasted in the
URL, it went immediately to the web site. The Google Help pages have a
multitude of problems of this type reported since early this year.
Some seem to be much more serious than mine. Well, it's not really a
problem, just interesting.

Isn't the internet wonderful and at the same time gives you pause. I
worked a Portugal station Saturday morning and he came right back to
me with my name. I had to wonder for a moment if we had worked before
or I had said my name. Then I remembered, he probably had high speed
access to QRZ and was a fast typist!

Folding wire in a fractal pattern to shorten an antenna is probably as
good as any other way of folding wire. Maybe better than some.

Lets make sure I follow, You are saying that radio communication
occurs because and antenna emits statically charged particle that then
imparts their charge to the receiving antenna when they strike the
antenna. Is this what you are saying.

Correct, Maxwell's laws referes only to the distributed loads which
remain in place no matter what you do to the wire. For way to long the
notion of straight radiators have been staked into the folk lore of
radio
by those who oppose change. Actually it was present members of this
particular group who attacked his ideas as a false technology without
presenting proof, only derision. A line eagerly joined by the pseudo
experts from the CB era, some of which remain today.

Let's see, dust or soot are particles and can be charged. The VOA,
BBC and Deutsche Welle have big, big tranmitters capable of generating
considerable dust storms that have been tracked by satellite since
Gauss was in knee pants.

Well, maybe not.

Electrons are particles that are charged (just one charge, and only
negative), but awfully difficult to rip out of an atom without a few
KV (doesn't sound like an HT will be up to the job, so despite
evidence to the contrary - all lies - HTs do not work UNLESS their
antenna has a filament, screen grid, and a surrounding plate with an
opposite charge of several hundred volts).

Photons are particles (maybe) that are NOT charged, otherwise if when
you rub a balloon (diamagnetic material) on your hair (diamagnetic
material), it (diamagnetic material) would glow like a night light
instead of attracting, um, dust (diamagnetic material) and soot
(diamagnetic material) with its feeble force.

As antennas are not diamagnetic material - contrary to experience, all
lies - then antennas do not work UNLESS you have photographic proof of
a soot or dust layer coating one (aka skin-depth).

I hope this helps.

Having tried this several different ways, my advice: Just shoot over
the tree. Trying to shoot between a set of branches in the tree may
sometimes make sense but I've never encountered a situation where it
was best.

Now, the gotcha is, if you shoot over the tree, you might also clear
the 3 or 5 trees behind that! What I do is use a fishing reel and
reach out and gently grab the fishing line after the ball clears the
first tree. This kills the forward momentum of the ball. Then: LET GO
and let the ball and line drop.

Cutting a slit in the tennis ball and loading it up with washers or
pennies can give it a little extra weight.

Yes, I've stranded a few tennis balls in trees over the years.

Tim N3QE.

When you apply a time varying current to a radiator you arrive at an
impedance derived by two resistances. Radiation resistance and skin
resistance.
The more efficient the radiator becomes the less skin resistance depth
is used where the loss is added to the radiation resistance. When the
current ceases to flow within the radiator resistance the radiation
resistance becomes a maximum which is what we seek. This suggests
that maximum radiation is created by current that flows outside the
metallic member and underneath the encapsulating particle or unbound
electron. With the current flowing along the joint of the materials 2
forces are applied underneath the encapsulating electrons.
These two forces are the same as gravity and the rotation of the
earth.

In a time varying current these same two forces are represented by displacement current encircling a static field in eddy current form. The twistin g action applies a poealing action on the unbound electron and the displacement current supplies the ejection force the result of which
is a straight line projection with spin impressed on the electron.
Now we know that radiation is created by an accelerating charge so we must consider where the acceleration comes from. When the electron is launched it passes thru the afore mentioned static fieldwhich is being interfered with by a field at right angles to the main current flow. When the particle enteres the static field in the area the external field is impinged upon the electron or particle is placed into an acceleration mode until it clears the static field where it achieves a speed which incidently was found to be the same as that measured for light. Now the electron which is now charged follows a straight line projection of mass with spin and a generated electrical field. It is now a particle or electron back into its original mode looking for a place to rest which means it is looking for a diamagnetic material that is resonant, the part that an amatuer has directed it at. It arrives at the receiving antenna with a thump dislodging existing particles where it disposers its electrical field upon the receiving radiator for processing
in a mirror actions to that taken on transmission.
This single electron is a exact example of point radiation which can be seen as an ejection from a point source containing distributed loads
Note that the particles projection is of a straight line without effect from gravity as it is exhibiting the reacting forces around earth(gravity and rotation in line with Newtons equations. This actually became into being when a particle of the sun impinged on its barrier thus breaking equilibrium with both a direct force and a bending or spin force now known as the BIG BANG. These same two forces generate all the vector forces that exist in the universe such as gravity, electricity, magnetism etc as well as the well known ribbon with a helical action that represents the DNA of human life.

We are going OT, but just to add a few more:
- the widely claimed, though undemonstrated, hazard caused by (low-level) radio waves demonstrates the corruption of the "green" parties around the world, which use that argument to threaten the cellular phone companies

- the unjustified panic for some deseases (mad cow, h2n1 swine flu) demonstrates the corruption of the organization who should look after our health

Hard to say. We know what is termed as Leptons which escape from the
sun and get taken along in the solar stream towards earth.Some where
along the line they apparently finish up as neutrinos.
What happens between these events is considered to be Higgs field
which creates change in the particles. Then there is the connection to

light and supposed photons which initially attached to particles and
we know that when the particles from the solar stream provide charge
to the earths magnetic boundary. But these are just dots in the story
that wait to be connected but there are many things unknown between
the points that we theoretically know of which we have no evidence.
At the moment we have the observations of the masters and to this day
there is contraversy about particles, waves and the emmission of light
where the masters observations and equations are still a question of
discussion. What I have done is to use the equations of the masters
and connected them in a different mathematical way such they provide
tracable links between the BIG BANG, the Standard model and radiation
that matches the computer derivitatation of
radiation that is in sync with the teachings of the masters especially
Maxwell, Gauss and of course the Faraday shield, all of which now seem
to fit together nicely. The true bottom line is that the use of
Maxwells equations where accountability is taken of all forces
involved
have in essense via computer programs provide authenticity to the idea
of point radiation which leads to efficient small volume antennas.
And following these edicts I have been able to make radiators of a
smnaller volume that is known in the present state of the art.

Incorrect.

The Y2K bug demonstrated that in many cases companies wouldn't listen to engineers, or more correctly, programmers. Some did, most didn't until very late. I was working on Y2K upgrades in 1991 at utility companies. Many other, less critical types waited until much later.

Most programs that really counted, like utility companies billing and control programs, were written in the 1960s and no one ever expected them to be used for even 10 years without replacement, let alone 30+. To blame engineers is foolish, since they had little to do with the programs in the first place, or the programmers, who could not foresee the future.

And some languages turned out not to have a Y2K "bug" even if you didn't handle the years correctly. Like Perl. In most cases the worst thing that happened was that it gave a 3 digit year where you expected 2. So year 2000 showed as 100. Wasn't a problem in calculations involving time spans.

And what little real bits of the Y2K bug that existed was SQUASHED before it ever got a chance to happen. By the next and a half generation of engineers and programmers. And management that finally understood how much they had to lose. At a tremendous cost, 95% of which was wasted because management was soooo worried.

If one would just read in succession the posts above one might get the impression that I sat at a desk while in deep thought until I connected the dots which provided a exp-lanation of radiation where the books stated that radiation in itself was not fully understood. That is so far from the truth. Going to the physics books one can see examples where the maxwell equations was proven in many ways by the use of contributingequations. One proof that you don't see is the gaussian static field as a proof possibly because we had a conflict in metrics ie cgs and MKS
which possibly authors did not want to use for fear of muddying the water. From my point of view I saw it as a transition from a static field to a dynamic field which in itself was swhat Maxwell equations were showing. Sharing this observation on this group and other places drew nothing but cat calls because of the sillines of connecting statics with electricity as presently known. Pursuit via computer programs and other thoughts regarding equilibrium allowed me to formulate an array
where equilibrrium was in existance and all elements were resonant in the form of a full wave. Thus my work on unwinantennas .com began because I had destroyed some old wives tales. Then the second patent came where again I focussed on FW antennas to obsolete the idea of ground planes which I did by folding the FW dipole into an end fed form but with the question remaining regarding my thoughts on the standard model. Needless to say it showed that a verticle must be tipped with respect to ground via the very nature of these two fectors representing gravity and rotation. Going back to the end fed folded full wave it can be seen that one could section the FW in calculus form
in the form of many square circuits. In fact it could be expanded more into mesh form where a transmitted circuit could be one of many in parallel and where I was able to measure a resonant point on a small piece of mesh. Thus the second patent started to grow when I changed a std helix to where the lumped load was cancelled and introducing the mesh radiator to a ground mounted form for top band
instead of the requirement for height. Thus multi frequency small antennas were formed the holy grail of radio.
So that is a rough explanation as to how I got to understand radiation in a different way from the books where as an engineer I started with

Gauss and Maxwell while placing all written theories to the side lines
and working from first principles as I now saw it. Of course looking
at my home page I made many samples and experiments along the way
where I now have a large Faraday cage radiator on the ground and
making a small loop mesh radiator to insert into the Faraday cage to
emulate velocity increase of a beam as with a fire nozzle and
Bernollis theorems where I can reduce the area of resting for
particles
where the number of particles remains a constant where equilibrium
requires a increase in velocity and a tighter beam.

Which all means, according to Lord Art, that an antenna won't radiate in deep space due to lack of the particles (that he isn't sure of the type of) won't be available to coat your antenna in the correct manner so that it will be able to make them leap from it.

Of course if a radio signal consisted of charged particles, like he claims, you could easily bend a radio signal with a static electric field or magnetic field, which you can't. Heck you could run a radio signal around right along with the protons in the Large Hadron Collider. Except for the fact that you can't.

Y2k was certainly no surprise to people in the programming field.
Most off those that it was going to have an effect on were already
aware long before the doomsday predictions began. I know I heard of
this in the 60's when I was in high school.

Antenna physically shortened by bending the wires is certainly not new
to amateur radio as any ham with a small yard will atest. To say that
these antennas will work without degradation when compared to their
unaltered counterparts is just wrong.

Jimmie.

Holy Cow! I've discovered the Holy Grail!

I beat you at your own game Art!

If these antennas work like you say, I should be able to make a beam
antenna to any specifications I'd like with magnets or charged plates.

I hereby claim that an antenna type made with charged plates surrounding
a dipole shall be called the K0TAR Unmodulated Electric Plate Beam
Antenna, and the type with cow magnets surrounding a dipole shall be
called the K0TAR Mystifying Magnetic Beam Antenna. And the type with
charged plates AND cow magnets be called the Super Whizbang
ElectroMagnetic Antenna.

Hmm. That last one could be a problem. Since Art has disproved that
there are really EM waves involved here.

I'll have to think about this some more.

I'll get back to you all later.

I found out the hard way. I prepared an expedition to Computer
Literacy and discovered they were closed. I was seriously bummed as
Stacy's in SF was too far away to drive.

I don't know exactly why they failed, but I think online shopping for
books might have killed them off.

This may help:

Comes from the illusion of control. Instead of learning from King Canute's demonstration to his courtiers of their folly, a demonstration so vivid we remember it today all over the world, although those who teach it to us deliberately in schools more often try to make him look like the fool while trying to control us and rear us in turn for control.

One reason I'm taking up SWL is that the internet has been great, most useful, but it easily undermines a sense of how large and complex the world is. SWL leaves no illusions about difficulty, distance, and luck, and fate. It reminds me of days when it wasn't so easy to believe in illusions of control.

This is true but it doesn't render an 'opposing' view false. People do various things, some change with fashion, maybe don't beleive they're getting value unless it's changed whimsically, bloated to look bigger than the competitor's offering... Others (like me) prefer small efficient modular systems whose parts serve long after and beyond any intent because their makers managed to focus on a singular issue while not losing sight of context while they worked, in effect future-proofing their design to some extent. This lets me adapt things where they won't just continue to work as is.

I think the Y2K 'bug' wasn't corruption, but folly. It only takes a few more bits to store the full year values, yet they were not used. No doubt some engineers did think of it. Similar problems happened in hard disk addressing. I think people are quickly learning that allocating storage for large addresses is MUCH cheaper than fixing it too late, several times a decade. Network addressing with IPv6 for example, that one might never have to change in all our future. We could populate the local group of stars with people before we ran out of addresses that way. (Although I guess many people are more likely to want to network toilets and toasters instead). Even Microsoft deserve a bit of credit with their 2-byte text allocations filled for years with alternating ASCII and zero bytes. Looked stupidly wasteful to me all those years but it's paying off now that Unicode usage extends so much. They evidently learned from Gates' assertion that 640 KB of RAM was more than enough for anyone.

While it's not easy to forsee the future, it IS easy to forsee that modest size addressing systems will be outdated fast, because any successful system gets adapted to more uses even if the total number of users doesn't change.

MIDI, used in music, has become a versatile machine control language, mainly because its inventors did think of this, in 1983, and MIDI continuously outlives its huge number of obituaries.

Yes. But in form of longitudinal waves. Electrons go out and come back from the end of radiator. For this reason he can wrote: "the idea of point radiation which leads to efficient small volume antennas.
And following these edicts I have been able to make radiators of a smnaller volume that is known in the present state of the art."

When electrons oscillate in a transmitter the voltage at the end of a radiator is doubled and the strong Gauss electric field is produced. Such waves are longitudinal.

>Exactly which particles are you saying are responsible for this?.

Here are many hypothesis. One of them is the Diracs electron see. So the electrons in the conductor kick the electrons in the space. But it is not important. Radio people should know which part of the radiator radiate and what the waves are: normal pressure waves or artifical TEM waves.

Ever consider what motivates the real experts to spend their time answering questions? I'm certainly no expert, but I do try to answer what little I can. For me it's learning something new and a karma boost in helping others learn and understand. Passing on my experiences and knowledge and all that.

Now, contrast that with the signal to noise ratio of this group. There isn't any question or discussion that doesn't get derailed into politics, philosophy, and some really off the wall physics. The dedicated experts will try to untangle the mess, and inject some reality into the discussion, with little results. All the time and effort spent in honestly answering on topic questions gets lost and wasted in the apparently endless and useless pseudo science discussions, none of which have any obvious applications to antennas. Little wonder the experts get tired of wasting their time, and go elsewhere.

I have some ideas on how to solve the problem, but since I'm sometimes part of the problem, I'll leave my foot in my mouth where it belongs. I suggest you also reflect on whether you're part of the solution or part of the problem.

More like natural philosophy or possibly fizzix. It's also more like
flocculation than precipitation. With a precipitate, all the rot just
settles to other bottom, where it's easy to separate and identify.
With flocculation, the rubbish seems to appear out of nowhere and turn
into flakes, while the topic of discussion remains suspended in
solution.
<http://en.wikipedia.org/wiki/Flocculation>

Let he who is free of off-topic, irrelevant, pseudo-science, and
useless comments, cast the first follow up.

ah, so now you are going to shoot particles from a fire hose faster
than light... that should be an interesting antenna. send me a
picture of it yesterday so i can comment on it the day before and we
could set up a whole backwards in time thread.

>so how do antennas encased in insulators work at all?

For this Maxwell invented the displacement current. It is oscillating
current in insulators. In insulators are charges which can not flow bat only
can oscillate. They can oscillate to and fro and/or rotate about some angle.

For the transverse wave they rotate.
For longitudinal to and fro.

But such seperate waves are only in the math. Real waves have always the two components. Always dominate the longitudinal.

So does this fractal antenna perform better than any other antenna? They seem like a solution so a specific problem, not as the sort of thing you would use if say you wanted high performance or had space to put a more conventional antenna into service.

> unaltered counterparts is just wrong.

That's the point I don't get, Jimmie. I don't know that anyone is
saying these antennas don't work. I think its a matter of just how well
they work. The answer is often "not very".

Yes, we can get a lot of things to radiate. Wires folded in a fractal
pattern will radiate, so will wires folded in a random pattern. Woe is
the day someone gets a patent on "random".

Antennas that are a tuned circuit on top of a length of coax will
radiate - at least the coax will.

So what? When I was a kid I made a little model of a radio telescope antenna out of copper wire and Aluminum foil. It was about 12 inches in diameter. Took a wire and attached it to an old radio. It worked better than no wire attached. Not that I'm going to promote it as a good antenna though.

Nope. Celebrate it. If it happens the patent system will lose credibility as a protection, let alone value for money, and people will rely on copyright law instead. Maybe that needs reform but the patent system is irredeemable in my view. The sooner it is terminally discredited the better.

That was off-topic, I know, but I withstood a few temptations already, and I won't get carried away. I don't expect everyone to agree so I won't argue it. if someome makes something work, and can get paid for the actual work, good for them, I don't think anyone should stand in the way of that. If people want to protect ideas, write them down, date them, and copyright them. That way plagiarism is preventable but suppression of anything remotely resembling it is not a legal option. And people won't be able to make claims for garbage while citing patents that shouldn't have been granted anyway, and wouldn't, if those granted could understand what was behind the obfuscating nonsense that some try to pass as a real invention.

I did google fractal. I can see that the different inventors do seem to be using similar fractals for their antennas. It looks to me as if what is needed for me to design my own without fear of infringement would be to just do some minor change, get my own patent, then there ya go.

Cohen's particular patents seem just fine as far as I can see.

Not specifically involved with fractals, but with the concept of patents in general, it looks as if we are seeing intellectual property rights run rampant. While no one should be denied the fruits of their cleverness, the system has devolved to the point where people are just ginning up patents with minor changes in hopes that someone infringes on them. Then they hit the jackpot, you bet.

The system kind of reminds me of the rednecks who play the disability lottery, hoping to get hurt so they can collect.

We have 2M packet node transceivers at a new government radio site. The new site owner requires isolators be installed on all transmitters. As you might surmise, it doesn't seem possible to do so on a simplex one RF port radio such an Alinco DR-135.

Anyone out there with some realistic suggestions on how we might manage to do this?

Maybe just an RF isolator in the AC line?

MTV

3491. Three Element Quad Reconstruction

Newsgroup: rec.radio.amateur.antenna
Date: 2009-12-09 21:49:29 UTC
From: Tom Horne <hornetd@gmail.com>
Message-ID: <f69ead4d-74b3-46ad-aa6b-4f200c3bdc2b@d9g2000prh.googlegroups.com>
Source record: 11503

I have to following quad parts that I got from a fella for whom I took a tower down. Three spiders, twelve fiberglass poles, three small copper coils, and a massive boom to mast fitting. I am wondering if it might be worth rehabilitating the original antenna which is a tri band 20, 15, 10 meter three element quad of unknown manufacture. I have two AB-952 masts with extension kits that I use for special event towers. I have a Hy-gain tri-band Yagi-Uda for one antenna but no suitable antenna to top the other tower for field day, SET, and so forth. I'm looking for insight from those who have actually assembled quads. Is it practical, if one is well organized to use a quad as a special event antenna? How long might it take to assemble once it is fully assembled and tested and then carefully dismantled into a well marked kit. I am open to hearing that there is an equal or better performer that would be easier to assemble for a height of only fifty feet. The positions I've read so far indicate a greater gain, a lower take off angle at any given height, as well as a quieter receiving performance for the quad. Naturally I would prefer real world experience to a theoretical discussion partially because I am not yet well educated enough in antenna theory to fully understand the theoretical arguments.

Hello Ed,

Is this because of intermodulation products due to the non-linear
behavior of the PA? If the site owner is technical, you might discuss
a band pass filter as this also reduces undesired mixing of other
signals in your equipment's PA.

Best regards,

Wim

Are you confusing an isolator with a duplexer?

You could probably do this with an isolator, a pair of SPDT coaxial
relays, and some modifications to the PTT circuitry between the rig
and the TNC.

You'd install the SPDT relays between the radio and the antenna.
Between the "normally closed" switchable ports, install a coaxial
number. Between the "normally open" ports, connect the isolator.

Take the PTT signal coming out of the TNC, and feed it to a bit of
circuitry (possibly analog, possibly discrete digital, possibly a
little 8-pin PIC micro). The effect of this circuitry would be detect
PTT from the TNC, drive a signal to the relays to switch them "on",
delay about 10 milliseconds (long enough for the relays to switch, and
stop bouncing), and then feed PTT to the radio. When PTT from the TNC
is deasserted, drop PTT to the radio immediately, wait around 10
milliseconds, and then turn off the relays.

The isolator has to go between the PA stage, after the low pass
filter, but before the T/R switch. That will require some surgery
inside the radio to bring out two coax cables to the external
isolator.

I'm rather surprised that a government site would allow a DR-135T
radio. While the DR-135T is perfectly suitable for a stand alone
packet radio application, such radios don't do very well in an high RF
polluted environment.

Has anyone done an intermod calculation for all the radios in the
building?

> Anyone out there with some realistic suggestions on how we might manage
>to do this?
> Ed K7AAT

See above. If the site manager is fairly liberal, you might be able
to convince him that a simple bandpass cavity will suffice. It should
work because your packet box is running simplex. Even if he demands
an isolator, you still should have some manner of cavity BPF in the
line. I don't mean a little tiny soda can size cavity, but rather
something larger, with skirts that are way down. See cavity on the
left:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/2m%20rx%20cavity.html>

That would be solving an entirely different problem.

At many sites, it's necessary to install an isolator/circulator
between each transmitter and antenna. This prevents strong RF signals
from *other* transmitters at the site from coming back down the
feedline into your energized transmitter, intermodulating with your
own signal in the transmitter's finals, and bleeding nasty intermod
products back out up into your antenna.

This is a bit tricky to do if your radio doesn't have separate
"transmit out" and "receive in" ports. If you stick an isolator
between a single-poort transceiver and its antenna, the receiver won't
hear the incoming signal very well at all.. most of the received
signal power will be circulated away into the circulator's dummy load.

You either need to open up the transceiver and separate out the TX and
RX ports, or figure some way to bypass the circulator (e.g. a pair of
relays) when receiving.

Thanks to those who have responded already. I was hoping for some elegant solution I had not thought of, but so far nothing has come to light. Also I was hoping there would be some way to implement this wihthout relays.... but maybe not.

Regarding the comment about breaking out the Rx line to a separate output... that might be possible but its solid state switching and would be somewhat tricky to implement right after this solid state PA module output.

One reason I hate the thought of adding antenna relays to switch the Rx around the isolator is that this is a busy packet node and I don't like the reliability issues a couple of added relays might add to a presently solid state switched radio.. . although I could do this if forced to.

We have operated at this site since before the new vault was built and all present customers simply moved over to it so to answer the question posed, no ... no calculations have been done... but the new owner "requires" isolators. The best solution for this situaion might be to gather a few respected technical persons who this non-technical site owner is familiar with and perhaps convince him this isn't necessary.

OR.. we could easily add a pass cavity of two and hope that this would passify him.

We will see.

I'm still open to another other new or inovative solutions.

Thanks.

Another option is to buy a second radio, and use it for the receive channel. Your existing transceiver would be used solely as a transmitter, and could thus be hard-wired to an isolator.

You'd need to run the receiver on a different antenna, or have some form of switchable protection circuit to keep it from having its brains blown out by the transmitter.

We have T/R switches using the stock reed relays that come with Mitrek
radios on several 420Mhz links. My guess about 1,000 cycles per day.
The average lifetime for the reeds is about 2 years. I've lost count
how many reeds I've replaced. Fortunately, Digikey has a nice
assortment of reeds. I hear the Mitrek packet boxes are about the
same, although that's not my headache. If you're going to do the
external T/R switch, think solid state.

>no calculations have been done...

Do them. I manage a local site stuffed full of assorted xmitters.
I've prevented disaster more than once with some simple calculations.

<http://www3.telus.net/PassiveRF/>
<http://www.tcstx.com/software/Intermodulation.cfm>

> but the new owner
>"requires" isolators.

That's just the beginning. The site I run is rather loose. Mostly
hams and junk. So far, there's been no need for a major cleanup,
although I'm tempted. From memory, some other sites require:
1. Circulators *AND* cavities on all xmitters.
2. Demonstrate that spurious tx rubbish is -60dB down.
3. Heliax everywhere.
4. No dissimilar metals on the coax connectors and adapters.
5. No nickel plating on anything carrying RF. (no Radio Shack junk)
6. All modems, routers, computers, and must be in a metal box with
RFI/EMI protection.
7. Remote on/off switching (to disable the xmitter if it goes
insane).
8. Posted current licenses (FCC requirement).
9. Lightning protection everywhere.
10. Shielded and grounded data lines (CAT5).

Here's what CDF (Cal Fire) requires to share their vault:
<http://webmain02.fire.ca.gov/pubs/issuance/8000/rvsapp.pdf>
I've seen worse.

Ah, I found one that's worse:
<http://www.elsinorepeak.com/documents.html>
Ummm... don't let the new site owner see these.

Incidentally, I spent several months trying to identify the source of an intermod mix that was wrecking one of the ham repeaters. It would come and go with no obvious pattern, making it difficult to find. I finally got lucky by breaking protocol and unplugging customers equipment while listening for changes. The last desperation act was to unplug the 117VAC to 24VDC battery charger for the diesel generator. That was it. The problem was that it was completely shielded in both the case and the in/out wires. It was also directly below the antenna structure, which is a low radiation location. The moral is "That which is most obvious correct, beyond all need of checking, is usually the problem". Do things the *RIGHT* way.

>The best solution for this situaion might be to
>gather a few respected technical persons who this non-technical site
>owner is familiar with and perhaps convince him this isn't necessary.

Well, intimidation does work. Make sure your respected technical people bring along some muscle. If that doesn't work, try beer or wine.

> OR.. we could easily add a pass cavity of two and hope that this
>would passify him.

The cavity will work well enough if you don't have any other xmitters on nearby frequencies in the building. However, as one of those technical types, my never humble opinion is that the DR-135T is not the best of radios and will need all the protection you can provide.

> I'm still open to another other new or inovative solutions.

Plan A:
Hybrid Ring Duplexer.
<http://www.repeater-builder.com/antenna/hybridring.html>
It should give enough isolation so that you can run the receiver full time without a T/R switch. The problem is that I'm not sure it will work on a single frequency. I gotta do some RTFM first. You'll still need to bring out the receiver input coax, but at least there's no external T/R switch or relays. Also, put something on the receiver input to keep from blowing it up if there's too much VSWR.

Plan B:
Build a clone of the internal DR-135T T/R antenna switch. Bring out the TX and RX coaxes externally. Install a cavity in the antenna line and an isolator in the TX line. Install the T/R switch near the antenna junction.

Plan C: Use 2 radios, one for TX and one for RX.

but you said that "conductor kick the electrons in the space", now its
not electrons? So which is it? do you believe in art and his
particles that get kicked off the diamagnetic elements, or in the
maxwell displacement current that requires no particles?

maxwell's math only describes the real waves and they are always
transverse. the only fictional mathematical waves are standing
waves... they aren't real waves, just figments of someone's bad math
meant to confuse poor amateurs.

Greater gain per element? The way I see it is the 3 el quad would
have slightly more gain only due to the slight extra gain of it's loop
driven element, vs a dipole driven element on a 3 el yagi.
Is the extra gain worth the extra trouble? Not to me, but mpg will
vary to the user..
Lower angles per a given height above ground? I'd have to model them
to compare, but I don't think it would be enough to worry about.
Lower noise levels? This one I don't agree with unless you are in
an area such as high altitudes where corona discharge might be an
issue.
For most normal uses, I don't believe the loop has any lower noise
than a dipole. Noise is RF just like any other signal. If a certain
antenna receives less noise than another, it would also receive
a lower level from desired signals if they were from the same
direction and angle. For the most part, I think the claims of lower
noise reception from loops vs dipoles are pretty much hooey, and
not worth worrying about.

By "special event" antenna, I assume you mean one which can
be hauled and erected at most any location. IE: much the same
as a "field day" antenna..
It's up to you, and the amount of work you want to deal with.
Would I use a 3 el quad for a special events or field day array?
Nope.. Too much work and maintenance for my blood. :(
For a portable beam that can be planted about anywhere I use
a short tiltover-crankup tower with a A4S planted on it.
http://home.comcast.net/~nm5k/fd01-1.jpg
The tower can fit in the back of my trucks, but I now have a
motorcycle trailer that can haul it all.
http://home.comcast.net/~nm5k/fd2.jpg
And even that setup is a bit of work, and requires more than
one person to erect. But it can be slapped together and cranked
into the air fairly fast if I have a few extra hands standing around.

The performance while not earthshaking is pretty good.
They won 10m phone with it the first year I tried it. And 20
and 15 are good on it too, being as it's pretty much full size
on all bands. IE: the 20/15m reflector is 32 feet.. And 10m
has it's own reflector which is at a better spacing than if it
were using the larger reflector for all three bands.
BTW, my rig doesn't go to 50 feet. Only about 31 feet..
But that's usually plenty high enough for gov work on the
higher bands.

Art fails to recongnize that if he were right all present day antenna
designs would be wrong an could not possibly work. Unfortunately for
Art we have been able to succesfully design antennas using mathmatics
with accurate preditable outcome for 100 years.

Of all the possibilites, I like this one the best... for reliability
and simplicity. We actually are antenna rich at this site. We also have a
small surplus of 2M transceivers, of which the receivers would probably
work just fine for packet.

If we can not negotiate an exemption from the management, I think this
is my first choice.

Thanks to all.

Ed

More:
<http://www.repeater-builder.com/antenna/site-stuff/radiositerules.html>
ALL LMR and PAGING TRANSMITTERS not equipped with a Pass-Notch
duplexer, will have an additional pass cavity installed to prevent
spurious emissions and minimize ambient RF noise to the other
equipment installed at this, and adjacent sites. An isolator
is also required between the transmitter and the cavity.
There are to be no PA decks, isolators or circulators looking
directly into an antenna, even a temporarily unused one.

I forgot to mention my pet peeve. Please label everything. Extra
credit for a block diagram showing where the wires and cables are
suppose to go. Here's mine:

Hold it now! The present aproach involving waves is correct but the waves themselves are a closed circuits without mass. The change from potential energy to kinetic energy is an accellerating term that is limited in a closed circuit by a decelleration of change or transformation of energy. For energy to be transported outside the boundary then mass is a requirement.

The same interaction goes on inside a cathode ray tube where it is mass or a particle that hits or impacts the inside of the screen. It is the same action that levitates an aluminum can(mass) and lofts it thru the air into a bin. In other words it is similar to the time taken for energy to change from a kinetic to a potential energy within mass.

An analogy is the amount of energy and time taken for heated water to change into steam.Gauss shows that to change from a static form to a dynamic form both time and mass are the metrics that are used. And that is true for both classical and particle physics where true analysis of the universe must be the same regardless of the methods used.

This does not mean that present radiators do not radiate, it means that present day antennas do not radiate efficiently as they only account for approx 90% of that which creates radiation. I state again, that when transporting energy there is an absolute necessity for mass, and it is mass that escapes from a energy field where the energy field is in the form of a closed circuit.

If you so desire you can fall in line with present day thinking that a particle is sometimes a wave but the same source clearly states that radiation is not fully understood, so the choice is yours tho it is acknoweledged as not fully explainable.

...
Hmmm. Are you suggesting that there is no displacement current in a
capacitance that uses a vacuum for dielectric?

Sigh. I'm glad I didn't have to learn E&M from reading r.r.a.a.

Cheers,
Tom

>but you said that "conductor kick the electrons in the space", now its
not electrons? So which is it? do you believe in art and his
particles that get kicked off the diamagnetic elements, or in the
maxwell displacement current that requires no particles?

In Maxwell times no electrons but only electricity. DC current flows only in
the closed circuit. AC current oscillate to and fro in the open circuit
because in insulator are also charges (electricity). The same electricity
was in the space. Maxwell did the description of such aether. Now no aether
but the Maxwell's math was modiffed by Heaviside.

>maxwell's math only describes the real waves and they are always
transverse.

Maxwell proposed the aether model with the transverse waves. There were the
vortex see and the idle gear.

> the only fictional mathematical waves are standing
waves... they aren't real waves, just figments of someone's bad math
meant to confuse poor amateurs.

When a wave reflects the amplitude is doubling. This doubling is real in the
acustics and in antennas.
The doubling is possible only in the compressible medium (air or electron
gas). The elecreicity in Maxwell's model and in the Heaviside math is
incompressible.

...
>Hmmm. Are you suggesting that there is no displacement current in a
capacitance that uses a vacuum for dielectric?

Yes. But it is not suggestion. The displacement current is necessary for the
incompressible electricity.
Now we know that the voltage is doubled (Marx high voltage generator) and
that means that the electron gas is compressible.
The dielectric between capacitor plates undergos the electrostriction.

>Sigh. I'm glad I didn't have to learn E&M from reading r.r.a.a.

But it is interesting to look at Maxwell's drawings to his model of the
vortex see with the idle gear.

sorry, but no. mass is not a requirement for transporting energy.

particles are particles and waves are waves unless you start talking quantum mechanics when all bets are off... fortunately quantum mechanics is not needed to discuss electromagnetic phenomena. if there were 10% missing energy in the maxwell equations i am quite sure it would have been found by now, we can measure waves much more accurately than that and have been able to for many years. the verifications of accuracy of nec and other programs based on maxwell's equations shows that quite well. if you don't believe it, find the missing terms and publish them in a peer reviewed journal so they can be shot full of holes.

Quite correct, one is an adjective and the other is a noun.
You can put a particle into a container, a wave you cannot

unless you start talking
> quantum mechanics when all bets are off...

An answer in science is acceptable if it matches well known facts
So here we have two sciences that squable about who is right and who
is wrong in describing the same phenomina

fortunately quantum
> mechanics is not needed to discuss electromagnetic phenomena. if
> there were 10% missing energy in the maxwell equations i am quite sure
> it would have been found by now,

A planar design of radiator does not conform with Maxwell's equations.
Following Maxwell's equations provides accountability of all forces
and NEC programs are very capable of showing this by divulging that
same 10% of missing energy.

we can measure waves much more
> accurately than that and have been able to for many years. the

> be shot full of holes.

The relevent term was added in the Maxwell corrections of his
equations. See the sample on my page.

How about supplying some facts to back up your claims so they can be
discussed?

photons are one thing that can carry energy but have no mass.
electric field interactions between electrons transfer energy with no
mass.

>
>

waves reside just fine in containers. take a look at cavity
resonators some day. in my dictionary 'wave' is a perfectly good noun
or verb, i see no use of it as an adjective... maybe you need a new
dictionary.

of course it does, maxwell's equations make no reference to the
geometry of conductors.

i make no claims, i am providing well know facts that easily disprove
your claims... it is therefore your obligation as the proponent of
this new theory to explain how your theory properly explains these
facts. and to get your theory accepted it is up to you to show how
your theory explains it BETTER than existing theories. THAT is how
the scientific method works, i should know because my employer decided
that part of my title is now 'Scientist'. I objected, insisting that
i wanted to put 'Mad' in front of it, but they wouldn't buy that this
time.

The photons and the fields are the math. In math are assumptions and
simplifications. Math is a piece to teach for students,
S*

On Thu, 10 Dec 2009 some gomer wrote:

>> Following Maxwell's equations provides accountability of all forces
>> and NEC programs are very capable of showing this by divulging that
>> same 10% of missing energy.
By the addition of considerable textual chaff (not included here),
this last demand is saved from being embarrassingly close to:
>> How about supplying some facts to back up your claims so they can be
>> discussed?

Any NEC program (expressly allowed in the first statement's premise)
will show that a dipole:
1. In free space;
2. x coordinate -0.245714 wavelength;
3. x coordinate 0.245714 wavelength;
4. 11 segments;
5. 1mm diameter copper wire;
6. excited at first resonance

Result: 97.5%

So, clearly the first claim of 10% missing energy is a product of
misinformation and is easily accounted by the allowable method (NEC)
contained within the erroneous statement.

However, let's examine the source of that 2.5% loss. If I were to
simply use NEC's capacity to render the copper into perfect wire (no
other changes made to the parts 1. through 6 above); then

Result: 99.7%

Whoops!!!!! no copper, and still not perfect?

This, too, is accountable within NEC as accumulated math error of too
few samples (segments). So, we simple amend part 4. above to increase
the number of segments to 111; then

Result: 100.00%

****

I can fully expect the wheeze that the antenna is not in equilibrium
(sic). Without pointing out that what is already 100.00% efficiency
could not possibly be improved upon, I will instead increase the
frequency of excitation to put that structure into equilibrium (sic);
then

Result: 100.00%
or 0 improvement.

Having indulged the fantasies of equilibrium (sic), it is time to press in the opposite direction, let's say to 1/10th equilibrium (sic); then

Result: 100.00%
Howsaboutthat!?

****

So, using the allowable tools to investigate the claim of a missing 10% efficiency, it has been shown that this claim is wholly without merit and lacks any demonstrable basis.

I don't expect any counter proof that will be expressed with the same professional level of specification offered here, nor performable within the 3 minutes it took me to do this (barring the time to type this all out).

As described elsewhere, by using RF bypass relays for receive, the
isolator can be installed as designed, with one port terminated.
(This rig still requires bandpass filtering to keep intermod products
from being generated in the front end of your receiver and being re-
radiated. Such EMI can be very nasty.)

I would just tin the braid and solder it to the outer shell. You can
make it look better with a little heat-shrink tubing.

While I hate the thought of such chattering relays and the inherant possiblity of degraded reliability on a busy packet node station, I must admit this is a very logical method. Taken under consideration.
Thanks, Sal.

Yes. My one afternoon with a spud gun was conclusive. That sucker will throw a potato hundreds of feet. My host that day insisted that nobody raise the barrel above about 30 degrees because the spuds would go over the woods and onto his neighbor's property, which we could not even see! Propellant is a one-second spritz of hair spray. Not sure what kind of line to insert through the potato, though. Kite-cord? Monofilament?

It's poor grade of Metal has a HIGH-RF Resistance. Unlike COPPER wire,

Those SLINKY Antennas, Get very WARM almost HOT, so you really
know they do work, but very very inefficient.

Like trying to Pump at 200 WATT STEREO into your electric shaver
or light bulb!!!.

If they were pure Copper, you'd have something to talk-About!

Try making a QSO on a Bed Spring VERSUS a Dipole or Loop antenna.

Same analogy........

Easy. Create a list of the most frequent posters. Include the number
of postings they create per month, and the number of original lines of
text they add each month (don't include quotes and blank lines).
Select the top 3 posters, that have the smallest ratio of postings to
new content. These are the ones that traditionally change the topic
with one or two line inflamatory remarks. When they appear, the
thread is sure to go awry.

Also create a list of first time posters, who do NOT start a thread,
but only comment on it. These are guaranteed topic drift candidates
as long time posters directly attack the new poster, rather than his
comments.

A 3rd class of posters are those that supply pure opinions, without
any substantiation, examples, or anecdotes. Any thread that starts
out this way, will invariably include an example demonstrating that
the original allegations are wrong. It's at this point, that the
thread will go off into the minutae of the example, drifting away from
the original opinions.

Please send my prize to the address below.

Total bummer, since I used to be able to flip through a $110 book and see if it was what I needed. Buying it, shipping it, finding out it was the wrong one or written like a student paper, and then having to return it are all a bit too much bother. I used to buy books on sight, having never even knew the book existed and it was a hot topic to me.

The kinds of super specialized books I buy are in the $200 range and are out of date sometimes before I get them. Science books mainly.

Please pardon the slightly off-topic subject. I'm giving a class at
my grandson's school next month and I'm going to include ham radio,
with some of the kids presumably getting on the air. Of course, an
unlicensed person can operate if a properly licensed control operator
is present. Is there a source of more detailed information? I
keyword searched Part 97 and found no surprises. I think good sense
prevails.

But:
If I set up two HTs to talk simplex across a room, how do I/we ID?
KD6VKW/Alfa and KD6VKW/Bravo, maybe?
Can the kids call CQ?
Do they ID with my callsign or must I provide the ID in my own
voice?
Are there other sticking points?

In the absence of official guidance, your opinions are welcome.
Thanks.

Sal, the only kind of people that would like to talk to kids is exactly the kind of people that you want to keep your little kids away from.

Why not go find a couple of el cheapo PRS handi-talkies (Personal Radio Service - 450 plus MHz) and let the kiddies talk to each other that way? Why bring ham radio into it at all?

The FCC rules are available to everyone for free at the FCC website. www.fcc.gov.

Don't ask too many questions.

Marconi would not have invented radio transmissions
according to FCC rules if he lived today.
We would still live without radio.

John
Yes you have to ID but not in your own voice. Yes the kids can call
CQ under your supervision. If you use the lowest power setting and an
unpopular simplex frequency for the unit to unit calls it is rather
unlikely that anyone except the kids and you will hear it. Check with
your club and find a woman operator to respond to the CQ. Smaller
children will respond better to a woman's voice.

>prevails.

It's mixed in under the term "control operator". That's the licensed
operator in charge of the station by the station owner. Note that
much of the wording comes from the days when there were seperate
station and operator licenses. The duties are scattered all over Part
97. For example:
<http://www.arrl.org/FandES/field/regulations/news/part97/b.html>

>But:
>If I set up two HTs to talk simplex across a room, how do I/we ID?
>KD6VKW/Alfa and KD6VKW/Bravo, maybe?

The same way you do during field day or any other multi-operator
station. Just the call sign of the station. If you want to get down
to details, see 97.119(c) which discusses "self assigned designators".
You could just use tactical call signs as in a typical emergency net,
but that would really be a stretch. As long as there's a licensed
operator in charge, and they ID every 10 minutes, you're fine.

>Can the kids call CQ?

Yes. They can do anything that the control operator allows.

>Do they ID with my callsign or must I provide the ID in my own
>voice?

They can ID on your behalf because it's a station license, not an
operator license.

>Are there other sticking points?

Yes. You'll bore the kids to death with such minutae and trivia.

>In the absence of official guidance, your opinions are welcome.

One of the harzards of being a licensed radio operator is that it
instantly tansforms one into a legal expert. If the rules were
obvious and simple, we wouldn't need devine, official, or amateur

guidance, but that's another rant.

The most effective song and dance I did in front of a Jr High Skool
class was tearing apart various cell phones, walkie talkies,
computahs, and consumer electronics to demonstrate that they should
not be afraid of such things. Unfortunately, the parents hated my
guts when the kids starting practicing what I showed them. Learn by
Destroying(tm).

2nd best was dragging in my collection of old cell phones including an
IMTS control head, various bag phones, and an unbelievable brick like
handset that's VERY heavy. I also brought an early Motorola tube type
Breaky-Backy with wet cells inside. Some of the stuff still works.

Nobody was interested in Morse Code until I mentioned that it could be
used for "secret communications". That means that the parents and
teachers couldn't understand what the kids were saying. Lots of
interest (and potential problems) there.

The problem with todays version of ham radio is that it's really
boring. Nobody wants to talk to someone around the world, when they
can pickup a POTS or cell phone and do it with much less effort and
expense. With the demise of Heathkit, building radios is no longer a
draw. The magic of radio is gone. So, show them what they can do
with radio. Weather stations, APRS, satellite, construction, etc are
a good start.

The magic hasn't gone - it's just been refined. The numbers of enthusiasts may drop, but those left will be more focussed and dedicated. The quantity is being replaced by quality. For every ten new hams who buy an off-the-shelf radio, play with it for a year or two, then lose interest, there is one in whom the spark is truly lit. Building is alive and well in the form of QRP. The satisfaction of operating a TX which is the product of your own efforts and ideas beats driving a commercial radio any day.

(There is a mirror to all this in the model aircraft hobby. Many now begin by buying a top-dollar almost-ready-to-fly radio controlled plane. All you need is money. Little achievement, little reward, other than the transient buzz of flying the thing. Same effect - 90 percent drop out, ten percent go on to greater things: building and designing their own creations).

Don't believe the prophets of doom who tell us that ham radio is dead. They're just pessimists and losers. Ignore them and move on.

Correct - The magic hasn't gone. Take 10GHz. A 10 GHz SSB setup can do well over 200 miles with only 2 watts with an old DSS dish. You can call CQ in a 10G contest off of a local 30 story building, or even better - a local rain cloud. The systems are normally built as transverters from kits. And learning is involved in construction as you figure out how to interface a 2m SSB rig to a transverter, and where you find mini hardline, and SMA relays for cheap. Using them teaches the user a lot about practical microwave propagation.

Interested persons from the Midwest or those from anywhere else check out www.nlrs.org. We are one of the most active microwave groups in the US.

Seems to me that "KD6VKW Portable 1" and and "KD6VKW Portable 2"
would be appropriate. The addition of arbitrary letters and or
numbers after your call sign could be misconstrued as meaning
something other than what you intend. The use of Portable 1, Portable
2, etc., is more straightforward and accurately describes the type of
conversation in progress.

>The magic hasn't gone - it's just been refined.

For someone that's been in the hobby from before I could (legally)
drive a car, the magic is gone. To someone new to the hobby,
communicating with peoples on the other side of the planet is
commonplace. Pickup a cell phone, dial, and talk. There's no magic
in that. In the past, showing potential new hams how it works got an
"amazing" reaction. These days, I get asked "what's all that noise"?
It's no longer a technical hobby, but more like a "radio sport". It's
no longer about building and refining a radio to the bleeding edge of
the state of the art. It's now what you can do with a radio.
Fortunately, there's plenty to do with a radio. I listed a few.
There's plenty more (contesting, CW, boat anchors, xmitter hunts,
microwave, field day, packet, meteor scatter, etc). Plenty to
interest a Jr High Skool brat, but you have to show them first. I
used to worry about overwhelming them. Not any more. I show them in
everything I can find and let them find their own inspiration. Oddly,
the local new hams seem to be coming from the 4-H Organization.

>The numbers of
>enthusiasts may drop, but those left will be more focussed and
>dedicated. The quantity is being replaced by quality.

There was a surge of new hams wanting to use ham radio as a cheap cell
phone. That didn't last, but it sure fattened the various club
treasuries. I'm not sure those remaining are more dedicated. Most of
the radio club members are 50 or more years old. There are younger
members, that also tend to be very technical, but they're disappointed
at the general lack of technical expertise of the older hams. Comments
like "how do you expect to operate a software defined radio without
any programming skills?" are common. I give at least one technical
talk a year to the local clubs. I can tell by the audience's faces
that only a few have a clue what I'm talking about. I passed out about
30 CD's with 4NEC2, EZNEC demo, and a zillion models at one meeting.
I think perhaps 1 or 2 people tried it.

>Don't believe the prophets of doom who tell us that ham radio is dead.
>They're just pessimists and losers. Ignore them and move on.

I like to think of myself of being part of the solution, rather than
the prophet of doom and despair. Please ignore me and move on.

Another lively form of ham radio exists where people use Pringles tubes and
such to make small directional relays for RF-based localised internet. While

the TCP protocol comes ready made, the spirit of ham radio is very alive in the way people coerce a pringles tube into doing these things.

Unfortunately if they are properly made, they are illegal to use in the US and other places in the world.

The EIRP limit in the US is 1W for portable/mobile and 4W for fixed (point to point use), a properly made Pringles antenna produces slightly over 4W with 100mW input.

Here it's even worse, the EIRP limit is 100mW, so any gain antenna is technicaly illegal, though 5dbi ones they are sold here.

It's become IMHO more like the spirit of modifiying CB rigs to transmit and receive in that little slice of radio spectrum between CB and the 10m ham band aka "freebanding" than the spirit of lawful, respectful ham radio.

Geoff.

Hi Geoff,

If it is done by a Ham radio operator. Ham radio operators (in the
US) are the ONLY class of radio operation that do NOT have a type
acceptance requirement.

There are, of course, certain restrictions.

The 13 cm band privileges for hams in the U.S. are not an exact
overlap for the license-free 802.11b/g frequencies. You can't assert
the use of your ham privileges if you're transmitting on channels not
covered by the ham authorizations.

You must ID properly (often done by setting the ESSID to the ham
callsign).

You may not encrypt the transmission for the purpose of obscuring its
meaning. [Some feel that encryption is permitted for the purpose of
ensuring that the link is used only by licensed hams, or for
"privacy". Some feel that encryption is OK if you make the actual
encryption key publicly available e.g. on a web site.]

If you have a valid U.S. ham license, and respect all of these (and
other) Part 97 ham restrictions, then you can legally use commercial
WiFi gear to transmit on these frequencies. Under those conditions,
you can use as much power as Part 97 will allow... the Part 15 rules
do not apply.

I remember making telephone calls to other countries when I was a little kid in the 60's. The Transatlantic cable was laid in the mid 19th century. People could talk a long way away then too. Worldwide communications pre-dates radio communications. It's a matter of infrastructure.

<some snippage>

Not trying to bust your chops or anything, Jeff, but if you have no more magic in you for Ham radio, its going to be really hard being part of the solution.

Not for a Hams in the USA, with a Tech or higher License, on the Ham portion of the 2.4 Ghz band... We can use up to 1 Kw output power, not in a Pringles can, but with the appropriate Feedhorn, and an old 8 ft TVRO Dish, Moon bounce is a very real activity. It is the Tracking Hardware that gets expensive.... that and the 2.4 Ghz TWT's.....

I think I will drop my oar into this one too.

Being able to call someone in China is not the same thing as calling out, and getting a response from someone in China. A.G. Bell's practical invention of telephony long preceded practical (or even impractical) radiotelephony and no one seemed to care, but many got excited.

And to invert the argument. When I lived in Europe in the late 50s early 60s, Paris had such a funky telephone system that reportedly you could dial a "special number" that put you into an open common trunk where others would have been already deep in spontaneous conversation. It was very popular and "exciting...." until they fixed it (in their own time, of course - for the French that could have been many years later).

I have a diverse collection of demonstrations for them, hoping to
catch each one of them with something they find interesting. I have a
handout with eight Morse Code characters on it, enough to spell out
some easy words, They're mostly 4th graders. I'm doing magnetism and
communications and showing how they relate. I taught school in the
Navy, but I have no experience with little kids, except my own. My
Navy students were almost always well-motivated but I have no idea
what the 4th graders are going to be like. They are all in the
Gifted And Talented Education program and I think it's either going
to be great or awful -- no in-between.

It probably wasn't "funky". It was just hacked.

It also existed in the US. The chances are that it was the same destination type as it was here. In the US you could dial a number that effectively put you into a conference. It was used for telco meet-me maintenance traffic. Neither person needed to know the other's number. I know someone that used to do music requests to their 6 MHz (plus/minus) pirate broadcasts using this hidden conference bridge. They were the first on the air as a pirate station in the US as far as I know.

I don't condone it, but it was a long time ago, and the persons involved have paid their dues. And are all good taxpaying citizens now.

Sal, who do you suppose that they will talk to if they did take the bait and
get a license and a radio?

I've heard kids calling CQ many times, only to go unanswered - even by me, I
shamefully admit. I leave my ham rigs running while I'm working in my shop,
so I seldom answer anyone's CQ if I'm busy working, so the kids weren't a
special case, although I did feel guilty that I didn't answer their call.

Perfect. That's the right idea. Lots of show and very little tell
(unless they ask).

>I have a
>handout with eight Morse Code characters on it, enough to spell out
>some easy words,

Good idea. Mind if I steal it?

>They're mostly 4th graders. I'm doing magnetism and
>communications and showing how they relate.

9-10 years old is the right age to start. Between 8 and 15, I tried
literally everything I could find. Cooking, guns, sewing, carpentry,
elecronics (buzzer and magnets), chemistry, fizzix, etc. Getting my
attention for only a few minutes was easy. More than an hour was
impossible. Somewhat later, I took the ones that were of interest and
went deeper. I still recall round the clock repeater building
sessions in my fathers garage.

>I taught school in the
>Navy, but I have no experience with little kids, except my own.

When I took teacher prep, one of the first exercises was to reduce my
vocabulary to about 9,000 words which was about right for a 12 year
old. I later found out that the typical 12 year old knew far more
words than officially recognized. Just avoid any technobabble with 3
or more syllables and you'll do ok. Try to get them to ask questions
and answer the questions at the same level as was asked.

>My
>Navy students were almost always well-motivated but I have no idea
>what the 4th graders are going to be like.

They will be out to see how far they can push or taunt you. Don't
fight it. Just be their friend and not their diciplinarian. If they
go over the top and riot, then maybe sacrifice the leaders for the
greater good. Smart kids are much easier to deal with than the
academic losers. My favorite line for getting them curious is "wanna
see what's inside" or "wanna know how this thing works"? Don't be
surprised if you get high level questions. Most of these kid so read

magazines and techy stuff online, mostly ammunition to make themselves look good in class. Be prepared to answer tough basic questions like "why does one radio talk around the world, while others just talk down the street"? You might learn as much from their questions as they're learning from your demo.

>They are all in the
>Gifted And Talented Education program and I think it's either going
>to be great or awful -- no in-between.

In the accellerated classes, they'll all be trying to show off how much (or little) they know.

I know what you mean because our experience has converged there.
Outside of the Navy, and just yesterday, I was Mentoring 3 of my high
school students to varying degrees of success. When asked how it
went, I responded "up, down, and sideways." Luckily this response is
not the typical experience. These kids are from the lower end of the
socio-economic spectrum, but the school system here in Seattle has
made an investment, and community (I do this through the NW Assoc. for
Biological Researcher) does its part to. Computer literacy is tops
(without the golden hand of Chairman Bill Gates being felt). From
their interest and drive, their challenged background (or challenged
emotional/developmental life) doesn't disrupt their momentum.

One of the most profound lectures I have ever read, insofar as
teaching science goes, dates back roughly 150 years to one of our own.
"The Chemical History of the Candle" by Michael Faraday is a series of
lectures by the master of inductance given to young students. It is
the classic of its type and sets the standard even to this day.

One might ponder about the significance of a history of the candle. In
one sense, it is quite complete to that heading alone. But beyond it,
and he goes vastly beyond it, there is coverage that is topical to the
current energy debate, the current green debate, and current to the
state of biology that is understandable by the mid-schooler on.

One point that still astonishes me is when Faraday makes the point
(and I will extrapolate to current capacities) that for every barrel
of oil burned, a barrel of water is produced in the combustion
process. I have to wonder at the plight of science understanding (not
just training) when I see huge flame geysers burning in the desert
(waste gas) of an oil rich country that has to import water:
"What the FUCK? Over"

Or make it a puzzle. Some text they're likely to know, maybe a long and eventful paragraph of Harry Potter or similar, and translate for a short line that uses only a few letters of the alphabet and that does not identify the source text or content, but allows substitution to fill in other words, completed by working out what other parts of the text are saying, or by simple elimination within a word. I never did learn Morse well, never needed to, but playing with that method with other people on an internet forum was by far the closest I ever got, and the most fun. Someone would paste something into a code translator, and instead of doing the reverse I'd start with the few I always remember, E,A,N,S,T,O,H, and build on those.

It might sound like a lot for a young child, but if more than one are keen to find out what's being said they won't need much motivating, that will take care of itself. They won't remember every letter, but most adults who type every day would be hard put to locate every letter on a QUERTY keyboard without actually looking at one, what is retained is the memory of an important process.

No one in their right mind is going to be running that much power -
being line of sight, at those frequencies, there isn't any point.

Regarding your hypothetical situation though, The likely outcome is that
the Amateur would be asked to turn down the power. They usually ask the
two parties to work together to get rid of the interference. But the
real onus is on the part 15 device owner. Dunno if you read the F.C.C.
enforcement actions, but the licensed service still "wins". BPL was an
attempt by economic interests to turn technical reality aside for
pecuniary reasons, but it looks like th elicensed services are going to
win that war now also. After the ARRL got hold of the original documents
the F.C.C. used during the run up to BPL, and founf out thet the
commission ignored their own engineers findings, then tried to hide that
fact, it kinda let the air outta that tire.

Thankyew! I'm reading it now. The first thing I am struck by is the readability of the thing. So much from that era was so hyperliterate.

Most of those places have borrowed the technology to extract the oil in the first place. It isn't inherent in their lifestyle. They probably don't know about the water because we didn't tell them. And we were just worried about the oil.

Excellent point however.

Most of the Wi-Fi installations are setup to go through walls where
power is helpful. Not exactly line of sight. Some of the outdoor
installations are installed by WISPs (Wireless Internet Service
Providers) that sometimes user maximum legal power amplifiers. You
can also buy relatively high power client radios:
<http://www.ubnt.com/products/xr2.php>
That's +28dBm or 630mw, which is considerably more power than the
typical 50mw radios. There are also bi-directional power amplifiers
allegedly sold only for ham, government, and industrial use only:
<http://www.ssbusa.com/kunamp1.html>
and the video equivalent:
<http://www.bhphotovideo.com/c/product/505472-REG/RF_Video_AMP_5000M_10_AMP_5000M_10_High_
Power.html>
from of all places a camera store. I've also helped identify and shut
down 3 such overpowered installations.

What's happening is as the 2.4GHz band gets more and more polluted,
some individuals seem to think that the solution is to increase their
TX power level. That's resulting in a very slow power war. The Wi-Fi
device manufacturers have caught on and are now advertising "high
power" devices, which seems to be anything over +20dBm (100mw).
Various pundits have predicted a power war, which fortunately hasn't
happened.

>Regarding your hypothetical situation though, The likely outcome is that
>the Amateur would be asked to turn down the power.

That's exactly what has happened in one of the situations that I was
involved. He didn't realize he was causing a problem and was very

cooperative. I also monitor the FCC enforcement actions:
<http://www.fcc.gov/eb/AmateurActions/Welcome.html>
and have not seen anything on 2.4 or 5.6GHz that required official
action. However, I do know of some warnings sent to WISPs over the
last 10 years or so for using too much power. So far so good.

>They usually ask the
>two parties to work together to get rid of the interference. But the
>real onus is on the part 15 device owner. Dunno if you read the F.C.C.
>enforcement actions, but the licensed service still "wins".

That's exactly the problem I mentioned. The licensed ham using 2.4Ghz
is within his rights to use 1Kw. He can also legally cause
interference to unlicensed devices without much consideration. So it
is written, and it must be. However, all it's going to take is a few
industry groups (i.e. lobbying interests) to claim that ham radio
operation on 2.4Ghz is somehow detrimental to the economy by impacting
Wi-Fi equipment sales, and I suspect there will be changes that impact
ham radio. Please consider my comments more as a warning than as a
denunciation.

>BPL was an
>attempt by economic interests to turn technical reality aside for
>pecuniary reasons, but it looks like th elicensed services are going to
>win that war now also.

BPL is going to die because the electric utility companies are not
seeing any revenue from the exercise, are getting some really bad
press, and really don't need the hassle. The interference issue gets
the press, but the decisions are always made on the basis of dollars.

>After the ARRL got hold of the original documents
>the F.C.C. used during the run up to BPL, and founf out thet the
>commission ignored their own engineers findings, then tried to hide that
>fact, it kinda let the air outta that tire.

True. Much credit to the ARRL for being able to do that. Still,
nothing has really changed at the FCC end. BPL systems that are
leaking well over established limits are still "working on the
problem". Most are still running in what is becoming a permanent
"trial" mode.
<http://p1k.arrl.org/~ehare/bpl/ex2.html>

Meanwhile, a rather large number of HomePlug devices, which is
essentially BPL for home internet, are being sold. They don't leak as
much RF power as real BPL systems, but still manage to make plenty of
noise:
<http://www.mds975.co.uk/Content/amateur_radio_BPL_interference.html>
Hmmm... It's QRN, not QRM. Oh well.
<http://p1k.arrl.org/~ehare/bpl/Testing_HomePlug.htm>
At least the ARRL is involved. Some HomePlug devices have
pre-programmed notch filters to reduce power on "sensitive"

frequencies which include ham bands.

LOL I showed showed some kids how to disassembe and reassemble a
desktop computer. I understand a few did well on the disassembly part
but not so well on putting it back together their parents computers.

That's the way we all learn. Next time, they'll do better. You've
hit on one of my many pet peeves. The skools are so afraid of
liability issues that any activity that involves potentially dangerous
tools or devices are proscribed by the administration. The result is
a generation (or two) that don't know which end of the soldering iron
to grab, don't know how to use hand tools, and have zero experience
with machinery beyond simple power tools.

They really have to learn to use such tools early in life or they'll
never learn. A friend of mine's father was an auto mechanic. He
didn't want his son to also become an auto mechanic. Every time his
son would pickup a tool, his father would take it away from him. It
worked. We met when he was about 40 years old. Despite practice and
some instruction, he was a total klutz with hand tool, and a hazard to
life and property with power tools. Try as he might, he couldn't
recover from the lack of childhood experience with tools. However, he
was far from useless. He taught me Unix and some programming in trade
for me maintaining his (Plexus and NCR) servers.

One of my standard birthday (and sometime Hanukah) gifts is a tool box
stuffed full of quality hand tools. I build the kit myself which
includes everything from jewelers screwdrivers to a claw hammer. When
I have time, I hot stamp the birthday brat's name into the plastic
handles, mostly to discourage anyone from borrowing tools. Years
later, the kit is invariably dispersed and half missing, but during
those years, the birthday brat gets some very useful experience with
hand tools.

I was encouraged to take things apart when I was fairly young. I had
my own tool collection by age 7 or so and was encouraged to use it. I

managed to break many things. My father and I would sit down, and he would fix it. One day, I decided to take apart a brass mantle wind-up clock. The main spring went boing. Instead of my father fixing it while I watched, I got to fix it, while he watched. I fumbled, blundered, and generally made a mess while my father offered advice, but no direct help. At about an hour a day, we got it back together and mostly working after about 12 days. I noticed that my father was sitting on his hands. When I asked about it much later, he said it wasn't to stop him from grabbing the clock and fixing it himself. It was to keep him from grabbing my throat and strangling me because I was doing such a lousy job. Years later, I was rebuilding his factory sewing machines and later worked on rebuilding teletype machines. Without that early experience, I wouldn't have had a chance.

Learn by Destroying(tm) which means if you haven't broken it, ripped it apart, and fixed it, you don't understand how it works.

But. The alligator syndrome gets nailed every time here, although with some dB recovered due to better receive front ends. But still doesn't overcome the 30 to 100mW coupled to negative gain antennas on the link back to the AP.

The semi-exception that I know of, as of about 2 years ago when my ex-employer ISP that did (somewhat successfully) muni wifi, was testing and eventually installed, Go Networks APs. They were the only ones at the time that could use 20W ERP because they were phased array antenna APs. And they mapped the vector vs MAC address so it knew the best antenna angle to your PC.

What "vector"? The beamwidth width was 120 degrees for Go Networks
and 60 degress for Vivato. That's not a beam. That's a barn door.
That nonsense got me rather irate when the FCC concluded that an
overpowerful alligator, with beam steering, will somehow cause less
interference than a sector antenna system.

Go Networks was one of the later vendors to hop on the alligator
bandwagon:
<http://wifinetnews.com/archives/2006/04/go_networks_slips_veil_on_cellularmesh_metro_wi-fi.html>
They picked up the fumble after Vivato dropped the ball.
<http://en.wikipedia.org/wiki/Vivato>
To add insult to injury, Go Networks somehow convinced the FCC that
120 degree wide steerable "beams" qualified for the higher power. I
could do better with common sector antennas. At least Vivato used 60
degree beams, which was marginally better. As I recall, their
literature had an illustrators imaginative drawing showing what might
be hundreds of beams with what appeared to be about 5 degree
beamwidth. The illustration also showed the steerable antenna hung on
a wall, thus eliminating half the "beams".

What I saw with the one Vivato 2210 controller I played with was that
the usable range was about the same as a lower powered omni or panel
system because of the alligator effect. The AP was deaf. So was
management.

Incidentally, one local Muni Wi-Fi network turned DOWN their mesh
nodes TX power when they were finally convinced that they were
creating almost all of their own interference. Things worked much
better when the access points and repeaters used approximately the
same tx power as the client radios.

Absolutely right on the power.

I was referring to the panel antennas, not the pole mount units, but
your point is well made. I didn't mean to imply that it was a good
solution.

I modeled the 4 vertical pole mount unit and it's nothing great. At
least the panel versions ended up with some front to back.

Unfortunately, few muni systems seem to use sector antennas. Probably because you can lose money just as easily with a cheap system as an expensive one.

I am just glad that I am no longer near the WiFi biz.

Reading this post made me smile, as it brought back so many memories. When I was a young'un, I had a curiosity that went way past what most people would call common sense. I disassembled household appliances to see what made them work. Unfortunately it wasn't until I was 16 or so that I could put them back together. I tried chemically boring a lawnmower engine - btw, while hydrochloric acid will attack an Aluminum cylinder wall very well, it isn't too controllable. 8^) I took so many things apart that it was starting to become a bit of a hardship, and my folks were at a loss, because grounding me just gave more time at home to find things to take apart.

My Grandfather found the answer. He worked at Bendix where they made car and other radios. There were rejects and prototype radios that the company would give away. Anyhow, he and I sat down and built a power supply, and then he let me have at the radios. Ground rules were that I had to limit my taking apart to the radios, or things my folks were throwing out.

That was the start of both my electronics interest, and furthered my total lack of fear to tear things apart. All I know is that it was about as much fun as I ever had.

That was the tactic for the BPL folks. It has to be faced down whenever they bring it up. The tail should never wag the dog. It becomes doomed anyhow, because when the device with special privileges starts interfering with other devices with special privileges, who wins then? We cannot do an "Animal Farm" Some are more equal than others situation without chaos.

BPL proponents allowed people to believe that they were going to just send the signals along the lines from some sort of "head end" site, and they would be there for the tapping. In fact, they were a last mile solution the Fiber would have to be run almost to the house, then the signal injected into a H-V line - the bpl signals could not survive going through transformers - finally a device to couple the BPL signal from the HV to the Household line after the transformer would allow the signal into the house.

That's bad technology on so many levels it's obvious that the decisions were based on economics and perhaps some politics (not R vs D, but the

idea that belief trumps science, that the intuitive idea of sending
multiple signals on one wire just has to work.

Are we going to bet our life on that H-V line isolator - injector never
failing closed, and allowing Several KV into our home electrical system?

But the final issue for me was that the source of the data signal had to
come almost to my house. Clean, yummy, digital goodness being degraded
to a shaky easy to disrupt DSL speed signal. No thanks, folks. But let's
talk about get me hooked directly into that fiber, pleeze!

> <http://p1k.arrl.org/~ehare/bpl/ex2.html>

Fortunately, they are going to eventually go away. Unless BPL is going
to become some sort of welfare system with companies sinking money into
it's maintenance for just a few customers.

I had always wondered what was going to happen to BPL systems when the
sunspot cycle hits it's peak.
I'd been assured that propagation wouldn't have any effect on it, but
we'll see.

> At least the ARRL is involved. Some HomePlug devices have
> pre-programmed notch filters to reduce power on "sensitive"
> frequencies which include ham bands.

All eventually doomed to failure.

If I might conjecture, I think that the current crop of EE's did not pay
any attention to RF while grooming themselves for the brave new future
of "Everything is digital". The HF bands are an unruly beast. They are
prone to static, they are prone to propagation, where at some times a
strong signal can't go much of anywhere, and at other times a milliwatt
works the world. And to make things worse, the propagation varies by
frequency.

For most digital wireless situations, you want a noise free, propagation free, short range system. HF will never satisfy these requirements. Some times at sunspot minimum, they might look a little better, but even then, they just aren't a good choice. Hell, VHF is only just usable. Gotta be well into UHF before you get good stable conditions

But The new crop of engineers and econo-politicians would like to impose their digital reality on sections of RF spectrum that just aren't going to cooperate.

3594. TLW Program problem

Newsgroup: rec.radio.amateur.antenna
Date: 2009-12-17 16:07:53 UTC
From: John Ferrell <jferrell13@triad.rr.com>
Message-ID: <2kkki5lc5qk0bgt7r2g1nhf60pee11bm8a@4ax.com>
Source record: 11556

I am having problems trying to use the TLW program from the ARRL antenna Book. The version is 3.0. An unsuccessful Google search plus the fact that I have the problem on two machines leads me to believe it is something I have done or am doing wrong. I believe it was working OK on both machines earlier. Both machines are running up to date XPPRO.

On one machine when I select the "Tuner" button the program does not come up. It does show an instance as a sub task of the TLW on the task bar at the bottom of my display. Clicking the subtask causes it to blink but nothing else. In the Windows Task Manager it shows as a process momentarily and then disappears.

On the other machine the tuner window comes up but the on choice that will display is the T-Network. I am certain this one worked well a short while back.

Both machines have had the program reinstalled.

Before my study of the L-Match continues I have four possible things I must do:
1-make TLW work in my environment.
2-do the calculations manually (rather not, I am both old & lazy) re:Chapter 25 latest ARRL Antenna Handbook.
3-G4FGQ programs (good possibility)
4-Find other affordable software for the task.

All suggestions considered!

John Ferrell W8CCW

>they bring it up.

Good luck. Money talks as do votes. Who's right? 800,000 hams or
perhaps 50 million Wi-Fi users backed by a 2000 members of the Wi-Fi
consortium:
<http://www.wi-fi.org/our_members.php>
David got lucky with Goliath but might not do so well against an
industry alliance.

>The tail should never wag the dog. It becomes doomed
>anyhow, because when the device with special privileges starts
>interfering with other devices with special privileges, who wins then?

That's easy. In a court-o-law, such issues are settled by whichever
party lasts the longest and has the biggest war chest. If those are
equal, the winner is decided by which one can bury the courts in the
most paper. The merits of the case are rarely relevant. Before the
FCC, it's now who presents the case, but who's behind those presenting
the case. The only time the underdog wins is if there's a sacred cow
involved, or if the chairman is on his way out and needs to make an
impression on the press.

>We cannot do an "Animal Farm" Some are more equal than others situation
>without chaos.

Fairness and equality are nice theories that take the back seat to
greed, money, power, politics, and public relations. I don't think
anyone ever accused the FCC of being "fair" to all parties.

>BPL proponents allowed people to believe that they were going to just
>send the signals along the lines from some sort of "head end" site, and

>they would be there for the tapping. In fact, they were a last mile

>from the HV to the Household line after the transformer would allow the
>signal into the house.

Yep, that's about it. It was also suppose to be a test, pilot, or
demonstration system, not a fully functional deployment. That wasn't
at the insistence of the FCC, but rather because the power companies
didn't know what was going to happen and wanted to pull the plug if
necessary. Never mind that anyone with a clue about internet topology
might note that the rather unstructured wiring tangle was going to be
both expensive and unmanageable.

>That's bad technology on so many levels it's obvious that the decisions
>were based on economics and perhaps some politics (not R vs D, but the
>idea that belief trumps science, that the intuitive idea of sending
>multiple signals on one wire just has to work.

Hey, I like to read science fiction. Having written a few business
plans, I some also write sci-fi. If the FCC wants to get into the
act, I have no problem. In this case, their own staff told them that
it wouldn't work, which they solved by selective suppression of
unfavorable reports. These days, technical decisions are not made by
Dilbert. They're made by the clueless Pointy Hair Boss.

>Are we going to bet our life on that H-V line isolator - injector never
>failing closed, and allowing Several KV into our home electrical system?

Yep. Any risk is justifiable in order to deliver cheap internet to
the GUM (great unwashed masses). If we sacrifice a few customers for
the greater good, I'm sure it can be justified or at least
rationalized.

>But the final issue for me was that the source of the data signal had to
>come almost to my house. Clean, yummy, digital goodness being degraded
>to a shaky easy to disrupt DSL speed signal. No thanks, folks. But let's
>talk about get me hooked directly into that fiber, pleeze!

How about FTTS (fiber through the sewer)?
<http://fiberopticnews.blogspot.com/2007/08/ftts-fiber-through-sewer.html>
It sorta solves the expensive right of way problem, but may still have
problems with topology and interface. "Don't flush the toilet right
now... I'm watching YouTube".

>> Meanwhile, a rather large number of HomePlug devices, which is
>> essentially BPL for home internet, are being sold.

>All eventually doomed to failure.

Really? Sales and product announcements for HomePlug AV devices seems
to be on the increase.

<http://www.homeplug.org>
There's talk of using HomePlug for home energy management as part of
the "Smart Grid" initiative.
<http://en.wikipedia.org/wiki/Smart_grid>
A few blurps of data from each house won't cause much interference,
but city wide, will probably make BPL look like a minor irritation.

>But The new crop of engineers and econo-politicians would like to impose
>their digital reality on sections of RF spectrum that just aren't going
>to cooperate.

Yeah, but their clients have made their money long before anyone
figures out it won't work. Some technically flawed RF based ideas
that have percolated to the top:
1. BPL
2. White Space
3. Terrestrial use of the Ka and Ku band shared with satellite TV.
4. Satellite broadcast radio with terrestrial repeaters.
5. 8VSB versus COFDM for digital TV.
6. Part 15 communications without automatic tx power control.
7. Narrow banding, spectrum rebranding, spectrum auctions, etc.
8.... I'm late. that should do for now. gotta run.

That sounds like a broken shortcut or that you're running the MSDOS
version (TLA.exe) from a Windoze shortcut. Try:
Start -> Programs -> ARRL Antenna Book -> TLW
instead of using the shortcut on the desktop.

>On the other machine the tuner window comes up but the on choice that
>will display is the T-Network. I am certain this one worked well a
>short while back.

Sounds like the program is corrupted. Uninstall, reboot, and
reinstall.

>1-make TLW work in my environment.

Get someone there who knows computahs. Have them run a virus scan,
spyware scan, scandisk, registry check, Windoze updates, and other
maintenance tasks.

>2-do the calculations manually (rather not, I am both old & lazy)
>re:Chapter 25 latest ARRL Antenna Handbook.

What calculations?

>3-G4FGQ programs (good possibility)

Argh. When I download it, the TLW3.EXE program says version 2.03 from
Jan 2005. I have no idea which is the latest version.

3599. Ultra-compact 2m antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-12-18 08:05:49 UTC
From: Robert Lacoste <see-alciom-dot-com@na.com>

Source record: 11561

Dear all,

For a quite specific application I'm looking for an antenna design with ideally the following characteristics, which are, I know, contradictory :

- 2m band
- TX (low power, less than 1W) & RX
- ultra compact, ideally able to fit in a 12-15cm x 5 cm x 5cm volume
- as omnidirectionnal as possible on the horizontal plane
- more or less vertical polarisation
- raisonnable gain for its size (-5 to 0 dBi ?)
- low dependency to nearby grounds (would be installed either at ground level or on a wall)
- could be narrow band (say 1MHz) but in that case with stable tuning...
- low cost

Not trivial, isn't it ? For the moment my best match is a dual helix antenna (two colinear helix, each made with a L/4 long wire, driven differentially), but performances and size are not optimal.

Any good idea ? Would small magnetic loops be usable in such high frequencies and small size ? Has someone already experimented other good designs ?

Thanks,
73s,
Robert

Hello Robert,

Loop antennas (from strip material) are an option when you accept a
figure-of-eigtht radiation pattern in the horizontal plane. When your
link budget has sufficient margin, a figure-of-eight pattern can be
accaptable for indoor applications as propagation can take place via
reflection.

For a strip material loop that covers 0.12*0.05 m^2, you may expect
about 17 pF tuning capacitance. That capacitor must be able to handle
some kV (at 1W input power). matching can be done, for example, with
a gamma match or just an inductive coupling loop.

Your may add capacitive end-plates to your helical dipole. The actual
wire length will reduce, hence giving better efficiency and some
bandwidth increase. With a good match, -5 dBi must be possible with 1

MHz BW (VSWR=2, in open air).

I have serious doubts about efficiency and tuning stability when in close proximity of materials. As fields close to the antenna are very strong, comparing to full size antennas with same input power, I expect significant loss in wall building materials and detuning. So the match to the transmitter will vary significantly.

You should use all the volume you have to get reasonable efficiency and useful bandwidth, so you will very likely not find a ready-to-build design that fits your needs.

Best regards,

Wim

a rubber duck or just a loaded vertical should do it. add a small
ground plane or counterpoise coiled in the allotted space and you may
even get better than 0dbi.

I thought I was doing that. The services performed by the TLW program are what I seek. I made the assumption that those interested in helping would already be acquainted with the program.

You have pointed out the likely trouble spots and I will check these first! I also have more information in that I have discovered that the TLW program is working properly on my backup system. I suspect that wherever TLW stores its session to session parameters has been corrupted with un computable data. I have run many absurd configurations while testing design limitations.

You asked the right questions to get me on track.

I prowled around the registry without anything looking interesting.
Upon examining the folder containing the tlw3.exe file I found a file
"TL.DEF" which I replaced from with the one from the working backup
machine and all is well!
I will now return to my matching studies...

Thanks for the help,
John Ferrell W8CCW

No point using a "short" aerial as the radiaton angle will be up in the sky
and coverage absolutely rubbish.
The easiest aerial you can make is from a piece of 300ohm ribbon cable.
It's a slim jim type aerial which has a low angle of radiation and will give
a brilliant coverage compared to expensive colinear aerials.
You can just roll it up and stick it in your pocket, then when you want
to use it - hang it from a curtain rail. or a tall structure. No need for
any
ground.

Nicely done. TL.DEF is created when you first run TLW. I assumed
wrongly that the settings were saved in the registry. It would have
been messy to fix if they were because uninstalling most programs
preserves the user settings in the registry. When you reinstall, the
problems just return.

Not so, at least not for the stated reason.

The radiation pattern of an "infinitesimally short" dipole (or very short monopole over a good ground) isn't very different from that of a half-wave dipole (or quarter-wave whip over a good ground). There's only a dB or so of difference in the shape of the patterns, at any angle.

The problem with short mono-/di-poles is that you need to add a whole bunch of loading to them, in order to make them resonant and easy to drive. The usual methods for such loading are electrically inefficient... much of the power ends up being burned up as heat in the coil.

It'd help to know a bit more about the intended installation/application of this particular antenna, in additional to the described physical parameters.

There might be some form of slot antenna which would do the trick.

I suppose the uninstall program was leaving the TL.DEF file and the
folders intact in the same manner. The problem remained after an
uninstall-install sequence. I simply removed the corrupted copy from
my laptop and a new TL.DEF file was created on the next execution.

My personal preference would be to always operate this way. Keeping
the parameters & execution info in the programs subfolder makes it
possible to sanitize as required.
Thanks again!

I've found that most programs will set user and program settings directly under a section names after the company, or the program itself, so a look at the 'about' dialog usually shows a name or two that can be used to search for in the registry. A look at whatever the search reveals will usually narrow it down correctly unless the keys and values are named so cryptically that they make no sense to anyone but the coder. Few try that hard to obfuscate, and most tend to verbosity in commenting and readability so it's usually easy to find a program's settings to remove a branch and renew it. Trial and other license settings are usually much better hidden, but those won't affect subleties of program operation unless features are limited by license types.

One thing worth doing is to back up the entire registry to a file before testing a new program, then doing it again to a new file after first install (and perhaps reboot if required). Comparing the two will show what if anything it added. The time taken to do this is always less than that consumed in solving problems related to not doing it. :)

Fortunately a lot of coders now agree. I think the infatuation with the registry is declining. What's really weird is that in *nix systems, BSD and Linux etc, that have different filing subsystems, it's not common practise to put related config files in the base dir for the executable, so arguably they'd have more use for a common registry than Windows does but they don't have one. Life is strange... On the other hand, BSD and all do tend to use human-readable and editable configs more so it's easier to change things and back them up reliably while the program isn't running.

3610. Sangean ATS-909 external antenna impedance??

Newsgroup: rec.radio.amateur.antenna

Does anyone know what the Sangean ATS-909's external antenna input impedance is?

I searched for days for documentation on that radio and found plenty, mods, schematics, service manuals, reviews, but no straight word on the impedance of that input! (Not even in the service manual specs). The only reference I found was a from a guy on a 7-page set of ham reviews, and all he said was that it was a mystery!

Maybe the only way to know is to start from the schematic but I don't know how, but here's the best schematic I could find:
http://eric.horsemensociety.info/TECH/images/ATS909_Schematic_A.gif
(Antenna input is near top right).
(Link appears to be dead, 403, forbidden. I'm sure it worked last week..)

What I really want to know is whether the ATS-909 will work ok with a long(ish) wire outside feeding a 50 ohm coax via a 9:1 transformer, or if that would cause more bother than connecting a wire directly to it and putting up with local noise picked up from nearby buildings.

I make one of these in an attempt to create an 80m dipole in my loft
and did work to some extent and my IC703 was OK with it. I took it
down in the end because as part of a 'fan dipole' it was fantastic
at picking electrical noise. You can see what I did at
http://www.radiowymsey.org/FanDipole/slinky.htm

Charlie.

just hook it up with the coax even without the transformer and it
should be fine.

There's a 1K0 pot across the input which is used as a cheap and cheerful
RF gain control. So i'd assume about 1K. You wouldn't have a problem
with the wire attached direct, but you'll get lots of front end
intermod, as it's wide open - just a low pass filter (presumably 30MHz
cut off)before the RF amp. A bit of preselection is pretty necessary for
an external wire of any size.

Really? Wouldn't that be 'matching' a fairly high impedance in the wire to the low 50 ohm coax, then risking further loss in unknown input impedance mismatch? I like the idea though, if I thought it would be that easy I might have tried it. :) If it's really ok I'll do it. I haven't got scope for a really long wire so I do need to try to minimise losses, I imagine..

Who cares what the impedance is for that radio. Unless you plan on putting
up an antenna for one very narrow band of frequencies, the impedance of the
system will be all over the place. YOu can probably run coax to the antenna
and never have any problems.

Front end intermod? Do you mean pickup from local active gain stages or other RF subcircuits in the receiver being picked back up by the wire antenna and makign sum/difference signals or similar effects?

Also, I see that pot now, (and noticed that it also affects the telescopic inbuilt antenna's pickup on SW (not FM as far as I know)), but I also see a lot of other parts associated with that part of the circuit. I don't know enough to be sure but it seems they might complicate the picture. If not, I don't know why the impedance seems to be a mystery. If it were well established I know my searches would found it so in triplicate by now...

Ok, so that's two people saying that could work, and sure, I won't be relying
on a single narrow range, I want to see what's out there and detectable. I
might want to limit peaks and troughs in sensitivity by using a 9:1
transformer though, as I read several times that it is a useful way to do
that for general SW listening via a long wire. That alone means I probably DO
need to care about impedance matching.

:)
I heard of that one I think, maybe even kept a copy. I developed habits of doing stuff manually though, and eventually using wxLua to script stuff. In the long run it turned out easier than finding stuff and testing it..

I do a registry lock too, so each boot it's the same. Easy to override at prompt by hitting ESC. On W98 though (I stay, obstinately), not at all sure how easy that kind of thing might be to solve with WXP and later. With W98.. locking, backups, all equally easy with a batch file or two. I agree with the philosophy of dumping system restore nonsense for a specialised tool. Ghost saves my hide more often than I can count.

I've just found a schematic JPG - 475Kb. It claims to be a "RK777", but
I think that's one of the 909's aliases. I can send it - mail me at john
at aultmore dot net.

You need an impedance matching device otherwise incorrectly called
"antenna tuning unit". It doesn't tune the antenna, it only matches the
impedance
for a given frequency. The main loss will be with the aerial NOT being
resonant at your chosen frequency.
The only way you are going to find out is try what people have suggested,
then compare the results for yourself.

The Sangean external antenna input is a 2.1mm jack which would
acommodate a high impedance long wire, as per the instructions:

"ANT-60 PORTABLE SW ANTENNA
Included with the ATS-909 is the Sangean ANT-60 Portable SW Antenna.
The antenna is plugged into
jack (26) labeled EXT AM ANT. When fully extended this antenna should
improve SW reception. For
maximum performance this antenna should be placed as high as possible
above the ground and in an
unobstructed area if possible."

Your idea of attaching the antenna via 50 ohm coax would probably be
below the impedance range of the jack, tho' I'm not sure you would
really hear much difference.

If the Sangean external antenna input were designed for 50 ohm coax,
it would probably have a coax jack, not the 2.1 mm jack.

The 'type' of connector - especially on something like a small portable
radio - is absolutely NO guide to the input impedance (which, actually
could be almost anything). It's often determined by the need to keep it
small. I have a small VHF/UHF TV set which use a 3.5mm audio jack.

I know that, it was the first thing I found, but it doesn't answer any
questions about impedance, especially if the radio you buy is second hand and
doesn't have the antenna wire with it.

> Your idea of attaching the antenna via 50 ohm coax would probably be

Agreed, which is why I don't assume it's 50 ohms, and I start looking for
answers. I think you're likely right that it might not make enough difference
to worry about though. If using coax can get the SNR higher I'm in business
so long as the signal is strong enough for the input's gain to use.

Thanks, that could be useful. I've heard of them, wasn't sure if I'd need
something beyond a means to reduce peaks and troughs in resonance or
sensitivity across bands while trying to match impedance though. I read some
old posts by John Doty (archived on web sites) that suggested that a single
device could be set and placed at the end of the antenna wire and grounded
there too, and then weatherproofed and ignored. :) It's an attractive idea.

Hey Lost,
This page has lots of good info,
http://www.hard-core-dx.com/nordicdx/antenna/feed/magbalun.html

Sounds like the N8KDV Transformer would work for you, but you
still don't know the input impedance of your radio. You could try
getting that info from Sangean.
The problem you have is whatever antenna you have the impedance changes
with frequency. If you find a band that interests you, build an antenna for
that band.
Here's another that shows how impedance changes with frequency, it's put
in
mismatch loss rather than resistance and reactance, but it gives the general
idea.

You might shoot an email to tech at C.Crane Co. -- a lot of their
branded radios are actually customized Sangeans...they might be able
to tell you the most effective antenna and/or the impedance of the
thing.

Oh yeah.. :) Saw that one. That was what I had in mind. It irons the bumps out. That guy mentions John Doty, his page was one of many I found while looking for John Doty's DIY transformer plans. (Still not found those).

The way I see it (hopefully this is right) is that those deep level variations really DO need smoothing out as described there, because they represent signal loss greater than is likely to be caused by other errors like basic mismatches, and possible overload at peaks as Europe has many strong SW stations. Again, if I can use coax to increase SNR by reducing noise out of nearby buildings, it reduces the problem to one of loss/gain.

As Anthony Alouitius StJohn Hancock pronounced: "Stone me, you've got to have something to start with!". Not that I'd trust his judgement as a radio ham. :)

That's my plan for the other end of the wire though, the question is whether I'll have trouble at the ATS-909 radio end if I use it. Though I guess the antenna matcher (misnamed 'tuner' as IanT mentioned in his post) can help, and probably further assist the business.

I'll probably try longwire straight to coax first just to see what results, then an earth rod to ground the coax far end, and then the 9:1 transformer, before considering the more complex adjustable impedance matcher though. Got other problems like money and dodgy neighbour problems to solve first too, which is why I'm saying more than doing right now (and gathering info). Once I start doing, I need to minimise the actions so I don't have more than reception issues to worry about.

Well most tuner/antenna matcher are designed to take the impedance that
the
antenna cable presents and transformer it to 50 ohms. Your problem is the
Sangean is probably not 50 ohms. So to do it all right, you need to know the
antenna impedance at the frequency of interest., transform that to 50 ohms,
send it down the 50 ohm coax then transform it up (guess) to 600 ohms for
the Sangean.
Here's a good plot of resistance and reactance vs frequency.
http://thebellringers.blogspot.com/2009/04/plot-of-impedance-vs-frequency.html
The top graph, (Blue Line) is resistance and the (Red Line) is reactance
plotted from
1Mhz to 30 Mhz. As you can see it swings wildly. One antenna won't do it
all.

It's going to have to do the best it can. :) though I might find scope to try a few variants, more than one shorter wire, for example. Just got to reduce trial and error because that's what might cause neighbourly upset.

That I like. I also saw your earlier link before but went back to reread what he (the Florentian Ham) said about antennas for apartments (That page looks like a CSS disaster but the advice is good), and especially the how-it-works paragraphs on longwire matching.

From what I can tell, it might not need a long or large antenna at all, so long as it doesn't have high resonance, sharp bandwidth, or noise. I imagined that if a small antenna (perhaps with capacitative or inductive loading) could cover the wide range from 1.7 MHz to 30 MHz without much modification then so long as common mode signals were strongly reduced, and the other problems solved, extra gain could be used between the coax and receiver, and that PDF shows a way to do it. I guess loading with deliberately higher resistance involved to damp resonances will be ok with a small antenna and a preamp if I can mount the antenna near a remote ground and get the coax right. I'll try to avoid complexity I find hard to grasp though.

I might also more easily find 30 feet straight upwards than in any other direction... Already got an FM 1/4 wave dipole out there doing just that.

Ah, but in reverse? :) I don't know if this is good thinking, but if the coax IS 50 ohms, could I not put the 50 ohm connection onto the coax and tweak the other end (on the input instead of the coax) impedance by watching the signal strength meter on the receiver?

(Might be undeed according to posts people made earlier that suggest that losses here might matter less than what happens on the longwire end of the coax).

Looking at it from the opposite angle, though: it's fairly common in
the HF bands for the signal level isn't the limiting factor in your
reception. Even an inefficiently-matched antenna can deliver enough
signal to overcome the self-noise of the front-end circuitry in your
receiver.

What limits your ability to receive, under these conditions, is band
noise and other spurious signals, which "drown out" the desired
signal. Improving the antenna matching wil have little or no benefit
in dealing with external noise. Neither will a preamp.

Now, using coax as a way of excluding some of the close-in interferers
isn't a bad idea at all. What you might want to consider doing, is
adding an active buffer at the longwire-to-coax feedpoint...
basically, a low-gain preamp (a few dB) designed to drive a 50-ohm
load efficiently and to overcome the (slight) signal losses in the
coax. Some people seem to favor the grounded-base or grounded-gate
broadband amplifier, as it has a modest gain, can be quite stable, and
has a good resistance to strong-signal overload. You could use a DC
inserter/block system to feed 9-12 volts up the same coax which
carries the signal down.

If you're really concerned about matching the resulting coax-carried
signal to your radio's antenna input, you could wind a fixed-ratio
broadband transformer with the correct impedance ratio.

Point taken, at least with the matching vs noise. Others have said it won't matter much and I see why. preamp might be another issue though, especially in light of 'amdx's post:

"http://www.kongsfjord.no/dl/Antennas/The%20Best%20Small%20Antennas%20For%20MW,%20LW,%20And%20SW%20rev%202.pdf

This is a good idea, though maybe the one I learned and reposted might do better, it has a very attractive aspect, as it drives a simple speaker wire. That stuff is cheap, (even the heavy stuff is cheap and durable, I use it already for solar power..), and effectively forms a very low loss balanced current loop that is isolated entirely from any current path anywhere else. I wouldn't even have to bury the feed line, I could likely just run it along the guide wire in a nearby chainlink fence or whatever is convenient because it will very effectively reject common mode noise. It might still benefit from a preamp current driver at the far end but as it uses a low impedance input at the near end to take care of common mode noise it should be fine, and a lot easier to get power to. :)

> If you're really concerned about matching the resulting coax-carried

Might try that, though more as an effort to extend learning than any need. Right now I'm really glad I asked here because these answers are good, and I now seem to have a better idea (the vertical long whip and balanced feed and Norton preamp scheme) than the longwire-and-balun-and-coax I'd originally intended. I haven't yet verified the new idea but it appears to be from someone who has demonstrated capability among a group of radio hams, and it certainly fits with what I know without contraindications, and it would be much easier to arrange safely and discreetly than any other scheme I've seen. The author even states permanently retiring his longwires and inverted L's and so forth in favour of a phased array of two of the vertical whip. I haven't got the 60 feet of space for the two he specifies, but I think I'll do ok with one.

Ideally you would adjust the impedance of the antenna to match 50 ohms
then attach your 50 ohm coax, then connect to a 50 ohm receiver. (you don't
have)
But trying to adjust an antenna that is way out there (say 4000 ohms with
200 Reactance)
from the shack is not an easy task.

I'm in agreement with those that say just put up a wire and listen.
Then pick your favorite band and put up a resonant antenna and compare the
two.
Then your learning something.

Right now I have no idea what my favourite band might be. :) I'll try the basic wire, I used to try that many years ago as a kid, in places where it was easy, on private land with space for it. But that was the seventies, in the country. Now I'm in an inner city full of mobile phones and computers, things have changed so much that I know it won't be the same. I like that 18' whip scheme you linked to though, I really like that one and want to try it.

Yes, I was a little diappointent, I remembered seeing a lot of other
antennas
from Dallas, but they seem to have been removed them from the site. I guess
once
he finds something that works better and is not terribly difficult to make,
he
drops previous setups.

You must admit that there was a certain amount of entertainment in Chip's
postings. If someone asked him a simple question, such as "how long was the
longest element on the antenna you built"....he could have just said "x
feet". Instead, he would post a 6 paragraph rant and direct the person
asking the question to some obscure publication.

I've always thought that BPL was a solution to getting metering and rate data to and from the household from the head end. A fairly low rate application. This has great value to the regulated side of the utility (smart grid, before it was known as such). The idea that it could be used for consumer data was probably promulgated by folks who wanted to sell bigger/better modems, and latch onto "let's wire america" kinds of funding. Especially if the unregulated side could get income from infrastructure installed by the regulated side.

Lost-

I agree that the "basic wire" antenna approach will almost certainly
work. At least you will get your feet wet. That is the kind of
external antenna most often used with that type of radio.

If you want to continue the search for input impedance, consider trying
something like an MFJ Antenna Analyzer (MFJ-259 or 269?), which uses a
sufficiently low signal level that it shouldn't hurt the radio. Instead
of analyzing the antenna, use it to analyze the input of the radio. You
can use the information to design a matching circuit, but you may find
that the improvement is disappointing for reasons already discussed.

I got a reply, but Sangean didn't tell them that either. :) But he says what many here do, that it doesn't matter that much, and that 50 ohm line should be ok.

One thing that keeps coming up is the need to make my own transformer for the far end, whatever scheme I use, and in that context I often see mention of a ferrite core: Amidon FT-114-75 (AL about 3000, permeability u=5000, about 1.14 inch outside diameter as described on one page). Cheap but apparently not easy to find in Britain. Does anyone know a current source of something equivalent to it? It's beginning to look like I should get a small handful of them. Another thing that might be better fetched locally is something like the broadband preamp for LW to >30 MHz sold by Kiwa Electronics. If anyone knows of one, please point me to it.. It's a Norton balanced input amp with gain of around 10 dB. Even if I don't need it I'd like to know where to find such things locally. I can likely build something based on the Dallas design in a PDF I found but a good picture of the construction would help, as I can't easily visualise the coil and former arrangements from the schematic.

I'll pass. :) I think the reason no-one knows is that as you (and others)
say, it's not important enough. What does seem important is to try to reduce
localised noise, and to break the current link to protect the radio input
from static discharges. Whether I use coax or a balanced loop made from
speaker wire, it loooks like my next step is to get Amidon FT-114-75 ferrite
cores to play with, and in Britain I can't easily do that, but if anyone
knows a local direct equivalent to them I can try that. I'll Google for
things that fit the description (AL about 3000, permeability u=5000, about
1.14 inch outside diameter) but I think it's wise to ask here to try to save
time.

You can probably at least start your experimentation using the common sort of interference-suppression ferrites that are found in many computer accessories - e.g. molded onto DC cords, VGA cables, USB cables, and so forth. Here in the U.S. these are easily available at electronics surplus stores, ham-fest flea markets, and other such sources.

In my experience, these tend to be a ferrite mix such as type 43, which is optimized for use at somewhat higher frequencies than HF/SWL... so they will probably not be optimal for your purposes. However, they can be made to work.

A few years ago I constructed a common-mode feedline choke for our local ARES/RACES ham station, to try to keep 40- and 80-meter signals from being carried back down the outside of the coax and into the building (our signal was audible on phones in the city's "911" emergency dispatch center... *not* good). I took several tubular computer-interference-suppression ferrite cores (large inner diameter), glued them end-to-end with cyanoacrylate, let them dry, and then ran some RG-8X coax through the center and back around the outside and through the center again. The coax looped through the tube of ferrites three times.

This resulted in an extremely effective common-mode choke. According to my MFJ antenna analyzer, the impedance looking up through the coax in the usual way (standard hookup, into a 50-ohm dummy load) was 50 ohms... the ferrites had no effect at all on the differential-mode signal in the coax.

But, when I measured the impedance along the braid (i.e. from the ground shell at one end of the coax, to the ground shell at the other... a DC short circuit), I couldn't get a reading at any frequency... the

meter just said "> 1500 ohms". Even at the lowest frequency of interest, these non-optimal ferrites added so much inductance to the common-mode signal path that they were blocking the feedline current flow very effectively.

[Unfortunately, we determined that the phone interference was caused by direct RF pickup by the phone wiring, which was in the "near field" of the antenna above the roof. It occurred even if we completely disconnected the building feedline, and fed the antenna directly from a radio located up on the roof. The feedline choke couldn't help us.]

In your situation, I'd guess that you could probably make an efficient feedline choke by using almost any surplus ferrite toroid which is sufficiently large to wind your feedline (coax or speaker wire) through it a few times. Or, use several surplus ferrite cores, end-to-end, and if they're large enough in diameter, loop the feedline down through the center more than once.

It won't be perfect (nor as good as if you used a ferrite optimized for use at lower frequencies) but it will probably help matters, and will give you some sense as to whether it makes sense to go to the trouble and expense of buying ferrites that are better for your purpose.

A complete ring is better, air gaps might make it harder to assess how good
it is unless you know enough (or have equipment) to make comparisons. I
don't. :) But I did find an appropriately sized type 43 ferrite ring on eBay
and put it on my watch list a few hours ago, so I guess this is what I'll buy
if I don't find better quickly. The seller has a few, I think.

I hadn't thought of this for common mode noise suppression but I will try it, sounds like a good idea. The rings I'm after are for the coupling at each end of the line though, 9:1 or 10:1 at far end, 1:1 at receiver end. But I guess that the clamp-on ferrite slug could be useful on the balanced line loop that runs between the rings. I've also wondered if that balanced line might better be a twisted pair with each twist perhaps 10 cm or so long to be sure that common mode really is common, but I have no idea if that's wise or required. Haven't seen anything to suggest I need to do it.

> It won't be perfect (nor as good as if you used a ferrite optimized

>

80 turns.. plus another 8 for the secondary.. I read they should be close turns, and the ring size was probably specified mainly to accomodate them all. I will try other ferrites and carbonyl iron power type cores and whatever else comes my way perhaps, I found four small toroids in a broken computer SMPU that might be fun to try. Ultimately though, I'm aiming for best shots because it's like plotting an unknown graph curve with only a few

samples, so the better the accuracy of each move, the better I can understand any discrepancy in any one of those moves.

I have a basic philosophy that is similar to Jeff Liebermann's 'Learn By Destroying' thing, as I also used to take stuff apart as a kid, and destroyed plenty, but actually apart from seeing what sort of build quality was acceptable and how discrete components were built, I didn't learn much beyond tool handling, the thing that taught me most was when I took apart something I had to put together again for fear of punishment if I failed and got found out. So the closer I get to starting with something like an ideal working part or whole, the faster I can figure out the meaning of significant excursions from that ideal. It's kind of like the argument of whether a kid should get his first bike new and working, or self-built from bits. I think the first way is right because it's the fastest way to know what working (and safety) really is, then start changing things, knowing what path was taken and how to get back without help. Works great with computers too...

Ive measured the input impedance of a few SW receivers and found them
to be in the 1Kohm ballpark for the most part. I did this by applying
a voltage through a series resistor to the frontend of the radio and
adjusting the value of the resistor until the voltage dropped by 50%.
If you have a schematic an analysis of the front end circuit might
give you and idea.

Ok. That fits with the 1K pot for RF attenuation in that radio, someone mentioned this and I wasn't sure if other parts might alter the picture, but I guess not by anything that matters. I'll be using a ferrite at the radio end of a balanced line so I guess I can experiment with turns count and watch the signal strength meter. Might not even need a preamp if that works.

If I'm thinking wrong, please stop me before I crash into something. :)

3655. HomeBrew Capacitors?

I have been successful at modeling and then constructing transmitter matching circuits at low power with common sizes of capacitors. Now I want to move up to the 1 KW power level. Inductors are easy enough to homebrew but capacitors are both expensive and scarce. Anyone have ideas or maybe experience in this area?

DigiKey has a good selection of High Voltage units (3 KV Plus) at modest cost but considering their size and the losses expected in the capacitors I don't think they can dissipate the heat...

lets go back to the beginning... this is what i would do.
1. hook up whatever coax you have to the radio and run it as far
outside away from the house as it will go.
2. hook up a wire directly to it as long as you can go in whatever
random direction you may be able to go
3. enjoy.

if in the future there are signals that just aren't strong enough, but
still above the local noise, then start playing around with either a
matching network or a preamp. but until you know how well the
receiver by itself works with the plain wire/coax you are wasting time
over designing something you probably won't need.

Hi John, Are you using L networks for matching? If so, then you want a variable capacitor to be able to match a variety of loads. TenTec sells a 500pf ~3kv variable capacitor kit for about $50 that I have used with good results. It is the one that they use in the antenna tuner that they sell. Takes about a hour or so to put together.

If you want some cheep low pf fixed caps use either RG-8 for real hv and RG-58 for just hv. Consult the data books for the pf/foot rating of the cable, or measure with Z meter or antenna analyzer.

You may find that a good RF ground more benificial than any particular
antenna. I discovered this while in the military and had a chance to
hook my little cheap portable Setico rx to an antenna made of 20ft of
emt conduit and the ground system on an abandoned comm unit. Lots of
good info arounf on RF grounds on the web and this group.

People working on "small magnetic loop" transmitting antennas have developed some homebrew approaches. These antennas present a highly inductive feedpoint impedance, and must be tuned to a high-Q match using a variable capacitor which can stand off very high voltages.

I've seen at least three types described:

(1) "Trombone" capacitors. These typically consist of a U-shaped piece of copper pipe (adjustable element), whose ends slide into two longer pieces of larger-diameter pipe that act as the connection terminals for the capacitor. The sliding pipe is insulated from the outer pipe - its ends are wrapped in sheets of a suitable dielectric (Teflon or Kapton sheet is often used). The cap can be adjusted by sliding the U in or out of the terminal pieces... often done via a worm-gear motor drive, attached to the center of the bottom of the U.

(2) "Butterfly" capacitors... two stator plates, one completely-insulated rotor plate, and suitable dielectric insulation sheets between them.

(3) "Sliding glass sheet" capacitors... plate glass dielectric, with a fixed metal sheet sitting below (as one terminal) and a metal sheet glued to the top of the glass (as the other terminal). Slide the glass sheet back and forth on the bottom metal sheet to vary the capacitance. Researching the dielectric and high-voltage properties of leaded window glass, borosilicate glass (Pyrex and similar), acrylic, polycarbonate, and Teflon sheets might be worthwhile.

Other (non-homebrew, but available-surplus) choices are large-gap air variable caps, and "doorknob" fixed-value transmitting capacitors. The former are often known as "cheese slicers"... and I've actually seen

some people home-brew them, using either sheet aluminum or brass, or
copper-clad PCB material for the stator and rotor plates.

Lots of idea, but the only high power experience I've had is design of
a VMOS NMR power amp in the early 1980's. Reading between your lines,
my guess is that you're building a tube amplifier.

>DigiKey has a good selection of High Voltage units (3 KV Plus) at

>
>John Ferrell W8CCW

For high voltage and high power, vacuum caps are a good way to go:
<http://en.wikipedia.org/wiki/Vacuum_variable_capacitor>

There are also porcelain capacitors:
<http://www.atceramics.com/products/power_capacitors.asp>

There are ceramic dielectic high voltage caps but they tend to be more
lossy than vacuum or porcelain.

Jennings vacuum caps. The voltages in the table are in Kv.
<http://www.jenningstech.com/ps/jen/caplist.cgi>

If you want to make your own, there are always Leyden Jars and window
glass with alternating layers of aluminum foil. I've used both for
Tesla coils.

I suggest you look at various existing KW amplifier designs and see
what they use.

I'm guessing that you're talking about capacitors in the few pF to low thousand pF range used in L matching etc.

(The other alternative is electrolytics in the power supply, where the common solution since the dawn of time has been series connected 450V units with equalizing resistors).

For fixed capacitors, a surplus source of "doorknob capacitors" is the standard way. Not cheap or available at the corner store but they are available. Try Ebay, where by far most of the parts you'll find are Russian, or rfparts.com.

For variable capacitors, if you don't want to find some old Hammarlunds or EF Johnsons or whatever, MFJ sells some new manufacture large air variables, and other people homebrew their own out of sheet metal, threaded rods, and nuts:

http://www.metaphoria.us/hamradio/DL5DBM_cap_plans.pdf

The only way it would do that is for a number of people to get together and
do a bulk buy. Some manufacturers will not allow this of course. The
mark-up
on goods by retailers is terrible. As you have spammed a radio amateur
group,
what is more appropriate than discussing Amateur Radio equipment. Let's
take
KENWOOD for example. As an employee I could buy *ANY* device made
by Kenwood at 30% of the retail price, that included VAT in the UK and
delivery charges for the 24hour courier.
So a radio costing £1000 would cost me a grand total of £300!
Major UK resellers will get more of a reduction if they buy so many radios
or
antennas. For example, the shop will be charged £300 for a Kenwood radio
and offer it for sale at £900 special offer. They still make £600 minimum
out
of that sale - but if you take out finance at 34% APR over 2 years you will
pay
back a fee for arranging finance, £2000 minimum, then a fee for paying your
last payment. So from £300 you end up paying out £2500!
Supermarkets also try a con trick by offering goods at "3 for the price of
2" or
"buy 1 get 1 half price". The reason for that is bulk buying, the
supermarket
will drive the price right down, but not change the retail price. When you
are
forced to buy lots of items they make even more money. People are fooled
by psychological tricks in advertising, they think they are getting a
bargain but
are really paying out far more than they would like to! One way to cut the
costs is to get a friend/neighbour to join your shopping trip, then you can
get
all the 2 for 1 offers and split the costs.
Amateur radio antennas are also overpriced.

The over welming importance of the Fractal antenna is that it
ALWAYS presents a resistive load when discounting proximetry effects.
Thus leaving the problems of efficiency to the "matching" issues.

I have had some luck cutting out non ferrous parts like this using a
router with a carbide bit. Fasten the metal to a template and feed it
into the router. too easy.

<-snip->

Thanks, all good info!
The application is to match individual antennas about 75 feet of coax
from the radio. Coax is way too lossy at high SWR's and open wire just
too cumbersome. I have a storage shed with a pretty good radial system
at the feed point. I suppose the best solution would be a high power
remote auto tuner but I am just not ready to commit that much to the
project!

A simple L match should seems the best alternative for the
experimenting. I will slow down until I fabricate/acquire the
necessary capacitors.

no, it doesn't. go re-read some of fracky's original posts and you
will find out that a dipole is the degenerate case of any fractal
folding algorithm, and since we all know dipoles exhibit non-resistive
impedances when not at resonance that statement is just simply wrong.

Apparently it is" Fractus" that is the company sueing several companies and not "Fractal"antennas. I thought they were one and the same companies,So I am in error. Thus I apologize for this error. So let it be clear, that it is not Chip and his company that is pursuing the other phone manufactures but another company of like name

With respect to Chip's designs. What I consider important is that his radiators do NOT contain, or produce, any lumped loads in their manufacture that are not canceled leaving just distributed loads. Thus for the given actual length of the radiator (the equivalent stretched radiator length) the impedance is strictly resistive, neglecting proximetry effects. This meets the intent of Maxwells equations where lumped loads DO NOT EXIST when accounting for all forces involved in radiation. The only deviation from Maxwell that I can see is that it does introduce sharp bends which also introduces phenomina with respect to current lamina flow, where excess eddy current flow is introduced, which is additive and not subject to cancellation.

Art, how does a current through a lumped inductance behave contrary to
Maxells equations?

That is pretty obvious! If you review Maxwell equations you will see
reference to root L.C, where L and C refers to distributed loads only
and is not inclusive of lumped loads. Adding a lumped load introduces
unbalance or a deviation from equilibrium, which is a fundamental when
reviewing the laws of the Masters.
Mathematics demands of every equation that the metrics MUST
cancel to zero. Thus all metrics involved must consist of pairs.
If one introduces a lumped load via building considerations then
another one has to be introduced so that the metrics are able to
cancel
out to zero.
In the case of the slinky antenna it thus demands that the windings
must be equal and opposite.

Gauss's boundary contains static particles

Faraday cage contains static particles

Both have a boundary that is conductive and thus can radiate.

Both radiate when a time varying field is applied

Both receive when transformed into a time varying field
provided when the magnetic and electric moves to cancellation

Both are applicable to Maxwell's equations for radiation

Both start and finish with a time varient current.

Both produce a charge by accelerating or removal of a charge via
deceleration of a particle.

The accelerant in both cases is the intersection of two closed fields.
(Electric field and a static field encircled by
the displacement current)

In both cases the particle has a straight line projection with spin

In both cases the particle vector angles equate exactly with that of
gravity and the Earth's rotation

Question ;
How does the particle (singular) referred to in each case act like a
wave or become a wave as stated in Classical Physics?

Faraday doesn't care about particles

>

>
> Both radiate when a time varying field is applied

both have a boundry, this is true. Faraday cages are conductive and
could radiate if properly excited. But gaussian surfaces are
conceptual and have not physical manifestation so can not be
conductive nor radiate, though radiative fields could pass through
them.

>
> Both receive when transformed into a time varying field

I have no idea what this means.

>
> Both are applicable to Maxwell's equations for radiation

Gaussian surfaces are part of maxwell's equations by his inclusion of
Gauss's law. the Faraday cage is a result of the effects of maxwell's
equations in a practical application.

>

Only after YOU add the time factor to Gauss's law.

>

I would like to see how you encircle a static field (which by
definition must be infinite in extent) by a displacement current.

right, maybe in your twisted world.

its all a matter of perspective. quite simple in fact so i'll leave
it as an exercise for the student...
show your work, papers due by 9am tomorrow.

Something for you to ponder, Art:

If we shine monochromatic light source through a pinhole, some
distance behind which there is a white screen, we'll see that the
light is diffracted by the pinhole. If we have two such pinholes near
each other, we'll see an interference pattern on the screen. If we
replace the screen with a sensitive detector such as a photomuliplier
with a small aperature which we can move over the area of the screen
it replaces, we can quantitatively map the intensity versus location
in that plane. If we reduce the intensity of the light source enough,
we can get to the point where the photomultiplier detects individual
photons at even the locations of greatest intensity. Eventually, we
can get to an intensity where apparently there is almost never more

than one photon at a time on a path from the source to the plane where the detector is located. If we count photons for long enough, though, we can map the intensity at that plane just as we did above. Now, will we see the same pattern, the same interference, the same _relative_ intensities, as we did when there were lots and lots of photons arriving at that plane? If so, why? If not, why not?

Cheers,
Tom

Hi Tom

Not to encourage the nuts, but I have to point out one weird part to your description. If you reduce the intensity until there is only one photons at a time in the dark box, that is if a photon comes through the hole on the right, and none comes through the hole on the left. They will still show an interference pattern. There is explanation but it takes someone who knows more physics than I do. But I've built an apparatus that show just this effect. Why, 40 years of building research and teaching equipment for physicists.

Tom,
Thank you for your thoughts which probably is a break out from the double slit experiment which by the way has the apearance of increased attacks.On the many physics forums on the net physics professors have now ban those who would suggest that those in physics could be wrong. I know little of optics so I can't do justice indebating your thoughts so please allow me to change the approach.
The discussion is about behavior like a wave ! Not that a particle IS a wave. The definition provided for a wave is indeterminate and different to that generally known. All I ask is for an fresh evaluation of the work by Maxwell, Gauss and now with the addition of Faraday known by his work as an experimenter and not by his knowledge of mathematics.
For me I am concentrating on the subject of radiation and not of light or photons that have little evidence to support them as part of the discussion.
To my knowledge the Faraday cage is well understood where isolation can occur with electric fields,magnetic fields an current flow from a tank circuit. Particles and charges held are a part of Faradays thoughts
and accepted in everyday physics. His experiments bears out the boundary theorems by Gauss and others with respect to static particles and the addition of charge.
From a radiation point of view the mathematical equation for both of these efforts are those of Maxwell.
Radiation is not fully explained purely because physics are responding first to mathematics instead of observables as with the past which has lead to trickery and assumptions.
It is for this reason I have posted the additions of Faraday which are really the experimental results of what this group stated of Gauss where it is "illegal" to add a time vaying field! So what I have done is widen the pot of facts as supplied, not by me, but those of the Masters,
where the trained observers of this group have more data to explain where the masters should have referred to waves and not static or

charged particles. If somebody wants to add so called facts such as
the known presence of a photon and how it turns into a wave to provide
light then be my guest as long as the abservables are factual
that match known facts as with a lonely jigsaw part that fits so
deftly within the area assigned of a puzzle.
Other than that we are left with the comments of "nuts" from those who
consider themselves superiour of mind compared to others.
Best regards
Art Unwin

Yes. This is fully stated on the web where explanations are provided
that challenge the double slit experiment. I expect the academics to
cry foul, take it personal and then to form together and chant that
they are "nuts" After all, physics professors declare the discussion
is over
and fully decided by them. If one suggests otherwise then they can be
banned.

If we count photons for long enough, though, we can map the intensity at that plane just as we did above. Now, will we see the same pattern, the same interference, the same _relative_ intensities, as we did when there were lots and lots of photons arriving at that plane? If so, why? If not, why not?

Cheers,
Tom

Art,

The same phenomena can also be demonstrated using microwaves. At UHF and VHF it allows signals to be received even though there is a solid mass between the transmitter and the receiver - signals can be received directly behind a tower block or skyscraper due purely to diffraction effects (so long as you are far enough behind the building). Hills and mountains can also be used as a diffraction edge at lower frequencies enabling reliable long range communications without direct line of sight.

Electromagnetic waves, photons and electrons, are all inextricably linked. The electromagnetic wave is constantly varying as it propogates so that measuring it at one point reveals the magnetic element and half a wavelength later, the electrical element.

For example, water is made up of hydrogen and oxygen atoms combined as H2O but displays properties that are completely different to either element in isolation. Why should electromagnetic waves be any different? The combination of electricity and magnetism as a "compound" would logically be expected to display properties that are different to electricity or magnetism in isolation. Hence the observed properties of electromagnetic radiation.

Regards

Mike G0ULI

Happy new year Mike
Again I cannot do justice to a debate in optics. At the same time I
recognise that different things can exhibit similar properties and
thus, like many others, I can state that they act like the same while
at the same time state that "they are NOT the same."

With respect to radiation I stick with the aproach of Newton and do not see enough evidence that suggest that a wave and a particle are interchangeable in terms of mass with that of a particle.
From my own point of view I liken it to the standard model where only two forces in combination with mass make up all of the Universe as we see it in that the particle of mass is the same but the propertise bestowed on it are different.
Thus I come back to the radiation aspect and see a clear path to a particle of mass where additional properties are added in line with the exchange of kinetic to potential energies. So I am back in interpreting
results from the same experiment without the two leaps required to jump the Grand Canyon. This is why I have gone back to the times that mathematics did not rule all and provide two instances where
the properties of the particle are one and the same and present them for others to determine how and why Newton was wrong. AS YET
no body has explained the properties of waves with respect to radiation.

Mike
Picking up from your point regarding H20and parts in isolation.
H2o is a compound or so where the electrons or particles of a bound
form. In other words they have a energty constituent added.
Now let us look at the surface of water which is diamagnetic where the
surface is completely covered by Unbound particles such that insects
can walk across it. These unbound particles or electrons are so
tenacious in finding a place to rest that they are able to form a hoop
stress around a droplet. We know that updraft imposes a charge on such
an arrangement when that same surface disipates and the charge
returned to earth bring the same particle or electron with it
In each case the difference in the particles in isolation is purely in
its energy component. Ala bound versus unbound.
Looking at a football at rest at the beginning of a match. When the
whistle blows various characteristics are applied to the football by
the addition or removal of energy. When the ball finally becomes to
rest
it reverts to equilibrium where the energy flow as stopped and the
ball no longer has the characteristics observed and is at rest.
Thus we see how the same analogy can be applied to a Faraday cage
where the characteristics show the extent of energy change but where
the carrier of such is always the same, an unbound electron.

Well, there IS a bit of a "zazzy" way... I have seen done on a very few factory connectors..... the connector is installed with very short braid...the short braid is fanned out a bit... the connector back end is pushed under the braid about 1/4", and the braid brought down tight over the back end... then a small bit of tinned copper wire is wrapped over that braid ... you will note that the back end of othe connector is bent in a fashion that makes this easy. Then that wire and braid is all soldered to the connector. A lot of work for really no gain, I think.... but it looks nice.

While I am on a roll let me compare a Faraday cage with what is known about radiators
Aperture in the books is a relative measure of gain. In otgher words the shere thatr encircles a radiator or array is symbiolic of total gain
(poyntings vector) and where with respoect to a sphere the energy contained within the sphere is equal to the energty outside of the sphere.
In the Faraday cage the outside surface is covered in charges carried by particles as is the inside surface so the areas can be considered equal and 100% efficient energy transfer. The total energy is realisable ONLY when transfered as a time varying current from the inside of the sphere.This being the addition of the charges carried by the particles on the inside and the outside of the conductive surface.
Thus this is the experimental results o0f Faraday that leads from Gauss to Maxwell.
With respect to radiators the analogy between the surface area of a sphere equates with the circle that encloses a radiator, say a yagi.
This is provided by Jasik as a approximation of gain by visualisation.
This same analogy was applied by Steven Guest on his antenna paper presented to the IEEE for an electrically small radiator' where he showed that by "crushing" a radiator into a state of equilibrium for insertion into a half hemisphere as per Gauss.
Thus with all this interlocking of facts when comparing a Faraday shield with a radiator opponents of the particle aproach are now in a position of showing an electrical field cancelling a magnetic field both of which are a measure of energy alone and not mass to produce a addition of fields so that somehow a time varying current is obtained
which a receiver can use.
Compare this with the proposition that a photon is a relatively unknown,assumed to be without mass in terms of mathematics that apparently is a breakaway of energy from mass in a similar form to a fireball. Frankly the idea of the eyeball being a small Faraday cage to manufacture a signal to the brain is a much better supposition by those who rule physics of the day.
Art
